1. Preface

This manual describes how the CoreMedia system integrates with HCL Commerce.

- Chapter 2, Overview [6] gives a short overview of the integration.
- Chapter 3, *Customizing HCL Commerce 9.0* [11] describes how you have to configure the commerce system to work with *CoreMedia Content Cloud*.
- Chapter 6, *Commerce-led Integration Scenario* [53] describes the commerce-led scenario and shows how you extend commerce pages with CMS fragments.
- Section 5.1, "Configuring the Commerce Adapter" [41] describes how you connect a CoreMedia web application with an HCL Commerce store via the Commerce Adapter.
- Section 6.7, "Link Building for Fragments" [85] describes deep links from fragments of the CMS system to pages of the Commerce system.
- Section 8.3, "Enabling Preview in Shop Context" [103] describes how you activate the preview of Commerce pages in *Studio*.
- Chapter 8, *Studio Integration of Commerce Content* [95] shows the eCommerce features integrated into *CoreMedia Studio*.
- Chapter 9, Commerce Caching [120] describes the CoreMedia cache for eCommerce entities.
- Chapter 10, The eCommerce API [128] describes the basics of the eCommerce API.
- Chapter 11, HCL Commerce REST Services used by CoreMedia [130] lists the REST services of HCL Management Center used by CoreMedia.

1.1 Audience

This manual is intended for architects and developers who want to connect *CoreMedia Content Cloud* with an eCommerce system and who want to learn about the concepts of the product. The reader should be familiar with *CoreMedia CMS*, *HCL Commerce*, *Spring*, *Maven*, *Chef* and *Docker*.

1.2 Typographic Conventions

CoreMedia uses different fonts and types in order to label different elements. The following table lists typographic conventions for this documentation:

Element	Typographic format	Example
Source code Command line entries Parameter and values Class and method names Packages and modules	Courier new	cm systeminfo start
Menu names and entries	Bold, linked with	Open the menu entry Format Normal
Field names CoreMedia Components Applications	Italic	Enter in the field <i>Heading</i> The <i>CoreMedia Component</i> Use <i>Chef</i>
Entries	In quotation marks	Enter "On"
(Simultaneously) pressed keys	Bracketed in "<>", linked with "+"	Press the keys <ctrl>+<a></ctrl>
Emphasis	Italic	It is <i>not</i> saved
Buttons	Bold, with square brackets	Click on the [OK] button
Code lines in code examples which continue in the next line	١	cm systeminfo ∖ -u user

Table 1.1. Typographic conventions

Preface | Typographic Conventions

In addition, these symbols can mark single paragraphs:

Pictograph	Description
i	Tip: This denotes a best practice or a recommendation.
	Warning: Please pay special attention to the text.
5	Danger: The violation of these rules causes severe damage.

Table 1.2. Pictographs

1.3 Change Record

This section includes a table with all major changes that have been made after the initial publication of this manual.

Section	Version	Description	

Table 1.3. Changes

2. Overview

This manual describes how the CoreMedia system integrates with *HCL Commerce Server*. You will learn how to add fragments from the CoreMedia system into a *HCL Commerce* generated site, how to access the *HCL Commerce* catalog from the CoreMedia system and how to develop with the *eCommerce API*.

In general CoreMedia Content Cloud offers two integration scenarios with HCL Commerce: Content-led and commerce-led [see Chapter 6, Commerce-led Integration Scenario [53]].

- In the commerce-led scenario, pages are delivered by the HCL Commerce system. The page navigation is determined by the catalog category structure and cannot be changed in the CMS. You can augment the categories and product detail pages with content from the CMS. Content and settings are also inherited along the catalog category structure.
- In the content-led scenario, pages are delivered by both systems, transparent for the user. You can manipulate the navigation through the catalog pages and add complete new navigation paths. You can augment product detail pages with content from the CMS. Categories are rendered from the CAE. However, content and settings are inherited along the catalog category structure.

Integration scenarios

2.1 Commerce Hub Architecture

Commerce Hub is the name for the CoreMedia concept which allows integrating different eCommerce systems against a stable API.

Figure 2.1, "Architectural overview of the Commerce Hub" [7] gives a rough overview of the architecture.

Figure 2.1. Architectural overview of the Commerce Hub

All CoreMedia components [CAE, Studio] that need access to the commerce system include a generic Commerce Hub Client. The client implements the CoreMedia eCommerce API. Therefore, you have a single, manufacturer independent API on CoreMedia side, for access to the commerce system.

The commerce system specific part exists in a service with the commerce system specific connector. The connector uses the API of the commerce system [often REST] to get the commerce data. In contrast, the generic Commerce Hub client and the Commerce Connector use gRPC for communication [see https://grpc.io/] for details.

Figure 2.2. More detailed architecture view

Overview | Commerce Hub Architecture

Figure 2.2, "More detailed architecture view" [7] shows the architecture in more detail. At the Commerce Hub Client, you only have to configure the URL of the service and some other options, while at the Commerce System Client, you have to configure the commerce system endpoints, cache sizes and some more features.

2.2 Commerce Hub API

The *Commerce Hub* API consists of a gRPC API used by the *generic client*, and a Java API which consists of the Entities API as a wrapper around the gRPC messages, and a Java Feature API, used by the specific *adapter services*.

The gRPC API

The gRPC API defines the messages and services used for the gRPC communication between *generic client* and *adapter service*. It is not necessary to access this API from any custom code. Access should be encapsulated, using the provided Java APIs, described below. In case the existing feature set does not fulfill all needs for a custom commerce integration, the gRPC API may be extended. CoreMedia provides two sample modules, showing a gRPC API extension in the *Commerce Adapter Mock*. Please have a look at the Section 3.2, "CoreMedia Commerce Adapter Mock" in *Custom Commerce Adapter Developer Manual*.

NOTE

By Default the base adapter exposes the gRPC ServerReflection service. It is used by the *CoreMedia Commerce Hub Client* to obtain available features.

The Java API

The Java API consists of two parts. The first part defines Java Entities as a wrapper around gRPC. It is used by the *generic client* and the server in the *base adapter*.

The second part is meant for server side only. It defines the Java Interfaces, called Repositories, the *adapter services* may implement for any needed feature. This API should be used as an entry point for commerce adapter development.

Request flow

The request flow, using the above described APIs, starting from the generic client is as follows. Please have a look at Figure 2.2, " More detailed architecture view " [7] first.

- The generic client sends a gRPC request to the vendor agnostic base adapter. The Entities API is used to convert the Java entity to the corresponding gRPC message.
- The gRPC service implementation in the base adapter receives the gRPC request and invokes the corresponding repository methods.

While the API definition of the repositories is placed in the *base adapter*, the implementation which is called here is part of a specific commerce adapter.

The commerce adapter uses its vendor specific implementation to obtain the requested data from the commerce system. The data is then mapped to a CoreMedia commerce entity as defined by the base adapter.

Finally, the service implementation in the *base adapter* converts the given entity back to a gRPC response and sends it back to the *generic client*.

3. The *generic client* receives the gRPC response and uses the Entities API to obtain and process the requested entity.

3. Customizing HCL Commerce 9.0

NOTE

Only required when you want to use the eCommerce Blueprint

In general, certain configuration files need to be adapted in the *HCL Commerce* workspace. Depending on your degree of already applied customization, you might need to merge the provided configuration snippets with your custom code.

This chapter also contains small configurations in the CoreMedia system. These tasks are highlighted in the margin.

NOTE

Deployment to *HCL Commerce* servers, including Staging, Production and Development, is not part of this manual. Please refer to appropriate HCL documentation in the info center at https://help.hcltechsw.com/commerce/9.0.0/install/concepts/v9enhance-ment.html

The configuration should be performed by an experienced RAD developer.

NOTE

This chapter does not apply to *HCL Commerce* 9.1 either. With *HCL Commerce* 9.1 no customizations are required. Please refer to Chapter 4, *Supporting HCL Commerce* 9.1 [38].

Scope of delivery

In order to connect *Content Cloud* with your *HCL Commerce* server you will get the following artifacts from CoreMedia:

- The customization package for the store server (websphere-commerce-crs archive). It contains the required customized crs-web package to be added to the CusDeploy directory of your store server Docker image.
- The customization package for the transaction server [websphere-commercets archive]. It contains the required customized code to be added to the CusDe ploy directory of your transaction server Docker image.
- The customization package for the search server [websphere-commercesearch archive]. It contains the required search configuration and search customization code to be added to the CusDeploy directory of your transaction server Docker image.
- The Sample Data for HCL Commerce archive [websphere-commercesample-data archive]. The archive contains sample data for the HCL system, which corresponds with the test data for the CoreMedia system in CoreMedia Blueprint.

You will find all files on the CoreMedia releases download page at https://releases.coremedia.com/cmcc-11

The customization involves the following aspects:

```
Installation steps
```

- 1. Section 3.1, "Building Custom Docker Image" [14] describes how to deploy the deployable custom packages in your *HCL Commerce*.
- 2. Section 3.2, "Preparing the RAD Workspace" [15] describes how to apply the required customization to your *HCL Commerce* workspace.
- Section 3.3, "Copy Libraries" [16] describes how to copy libraries to your HCL Commerce workspace.
- 4. Section 3.4, "Configuring the Search" [17] describes how you have to add the Core-Media search profile and the Solr index. This enables the CoreMedia system to get additional information necessary for the integration.
- Section 3.5, "Extending REST Resources to BOD Mapping" [22] describes how you have to configure the mapping of REST resources to the Business Object Document nouns.
- 6. Section 3.6, "Configuring REST Handlers" [23] describes which REST handlers you have to add and configure.
- Section 3.7, "Applying Changes to the Management Center" [24] describes the deployment of the Management Center customization.
- Section 3.8, "Deploying the CoreMedia Fragment Connector" [25] describes the deployment of the fragment connector, which renders content from *Content Cloud* as fragments to *HCL Commerce* pages.
- 9. Section 3.9, "Customizing HCL Commerce JSPs" [30] describes how to apply customizations to *HCL Commerce* JSPs.
- 10. Section 3.10, "Deploying the CoreMedia Widgets" [31] describes the deployment of the CoreMedia widgets, which can be used to add content or assets from *Content Cloud* to *HCL Commerce* pages using the fragment connector.

- 11. Section 3.11, "Setting up SEO URLs for CoreMedia Pages" [35] describes how to set up SEO URLs for CoreMedia Pages.
- 12. Section 3.12, "Deploying the CoreMedia Catalog Data" [37] describes how to import the CoreMedia catalog content from the Sample archive into the *HCL Commerce*.

NOTE

In the following sections WCDE-INSTALL stands for the installation directory of your HCL Commerce RAD installation.

i

3.1 Building Custom Docker Image

CoreMedia Content Cloud integrates with *HCL Commerce* 9 using the Commerce REST API, therefore you have to deploy the custom packages in the *HCL Commerce*. These custom packages are for the remote store server, the transaction server and the search server.

WARNING

Only follow these instructions when you have no other customizations in your *HCL Commerce Server*. Otherwise, you have to adapt your RAD workspace as described in the other sections of this chapter and create new deployable custom packages.

The following procedure shows how to build the custom Docker images from the customized packages that include the customization code.

- 1. Create separate CusDeploy directories for the remote store server, the transaction server and the search server docker image. For example,
 - /opt/WebSphere/store/CusDeploy
 - /opt/WebSphere/app/CusDeploy
 - /opt/WebSphere/search/CusDeploy
- 2. Extract every customization packages to the appropriate directory. For example,
 - websphere-commerce-crs archive to /opt/WebSphere/store/CusDe ploy
 - websphere-commerce-ts archive to /opt/WebSphere/app/CusDeploy
 - websphere-commerce-search archive to /opt/WebSphere/search/Cus Deploy
- In order to create or update the Dockerfile to build each custom docker image, you need to:
 - a. copyCusDeploy directory to /SETUP/Cus directory.
 - b. run applyCustomization.sh script.
- 4. Stop and remove the running docker containers.
- Run the docker compose command to build the new custom images. For example, docker compose -f docker-compose.yml build

CONTENT CLOUD

Deployment Procedure

3.2 Preparing the RAD Workspace

CoreMedia Content Cloud integrates with *HCL Commerce* using the Commerce REST API, therefore you have to deploy/enable all the REST modules in the *HCL Commerce* work-space for *Content Cloud* to function properly. These modules include: Rest and Search modules.

The *HCL Commerce Workspace* archives (download at https://releases.coremedia.com/cmcc-11 contain all new and extended files required to install *Content Cloud* in the *HCL Commerce* RAD workspace. In principle, you can copy the workspaces on top of a fresh Aurora RAD workspace, but only when you do not already have customizations. Make sure you download the Zip archive that matches your WebSphere Commerce version. REST modules

Content of the ZIP file

WARNING

If you have already customized the Aurora RAD workspace, you cannot copy the Core-Media Zip content above it, because this would overwrite the former changes. In this case, unzip the files and add and merge the files manually as described in the subsequent sections. ł

3.3 Copy Libraries

Copy the libraries of the Code/ts-app/lib folder of the transaction server archive file into the HCL RAD workspace folder workspace/WC/lib/

Make sure that the lc-connector library from the CoreMedia workspace archive are in the corresponding locations of the Stores workspace: workspace/crsweb/WebContent/WEB-INF/lib/lc-connector-<version>.jar or workspace/Stores/WebContent/WEB-INF/lib/lc-connector-<version>.jar

3.4 Configuring the Search

WebSphere Commerce search provides enhanced search functionality to a store and also influences the search results by using search term association and search-based merchandising rules. In this section you will adapt WebSphere Commerce search to allow *Content Cloud* to leverage these search features. This includes browsing and searching of all catalog assets in *CoreMedia Studio* which is the editorial interface of *Content Cloud*. The configuration consists of two tasks:

- 1. Add the search profiles
- 2. Add a new field to the Solr index

3.4.1 Search Customization in *HCL Commerce* 9

Search Customization in *HCL Commerce* 9 take place inside the search server and the transaction server. All the customizations that take place inside the search server [search profiles and search schemas] are provided in the websphere-commerce-search archive and all search-related customizations that take place on the transaction server [search index preprocessing] are provided under the xml/search folder in the websphere-commerce-ts archive.

Search Customization

The project directories and any relevant subdirectories and files are listed in the following table.

Customization	Server (con- tainer)	Location
Preprocess configuration files	Transaction server	 xml\search\dataImport\v3\db2\wc- dataimport-preprocess-custom.xml xml\search\dataImport\v3\db2\wc- dataimport-preprocess-x-final build.xml
Solr related configuration files	Search server	<pre>search-config-ext\src\index\managed- solr\config\v3*</pre>

Customization	Server (con- tainer)	Location
Search configuration files	Search server	<pre>search-config-ext\src\runtime\config</pre>

Table 3.1. Search customization configuration

3.4.2 Adding Search Profiles

In WebSphere Commerce Search, search profiles [defined in the wc-search.xml configuration file] are used to control the storefront search experience at a page level by grouping sets of search runtime parameters. The search runtime parameters set needs to be extended to support the feature set introduced by *Content Cloud*.

The search customization can be found in the Code/search-app/searchconfig-ext.jar of the search server archive file.

Content Cloud requires additional information like SEO identifier or pricing which the WebSphere Commerce REST API does not provide by default. Providing this information via REST API is achieved by customizing the wc-search.xml configuration file to include that information.

To change/add the value of an existing property in the WebSphere Commerce search configuration file, you have to create a customized version of the search configuration file and add a profile to that file. Follow the steps below to customize the search profiles:

1. Add the search profiles:

Open the file WCDE-INSTALL/workspace/search-configext/src/runtime/config/com.ibm.commerce.search/wcsearch.xml in the *HCL Commerce Workspace* and copy all the config:pro file definitions with a name starting with CoreMedia to the corresponding file in your HCL RAD workspace.

You have to extend the existing REST API search handlers to provide the additional information now exposed by the search profiles.

Change the search profile for existing search based REST handlers by creating/updating the file WCDE-INSTALL/workspace/search-configext/src/runtime/config/com.ibm.commerce.rest/wc-restresourceconfig.xml with the corresponding changes from the *HCL Commerce Workspace* archive. Additional information for Commerce Cloud

3.4.3 Enabling Dynamic Pricing

Dynamic Pricing supports different prices for different price rules. By default, the feature is disabled.

You activate dynamic pricing by an update of the STORECONF table. Set the wc.search.priceMode property in the STORECONF table to value "2". See also https://help.hcltechsw.com/commerce/9.0.0/search/concepts/csdsearchstoreconf.html

3.4.4 Customizing the HCL Commerce Solr Index

Content Cloud comes with Solr schema customizations to be applied to the HCL Commerce Solr schema definition.

The schema customization can be found in the search server zip file below SEARCH-ZIP/Code/search-app/search-config-ext/index/managedsolr/config/v3/CatalogEntry/x-schema.xml and SEARCH-ZIP/Code/search-app/search-config-ext/index/managedsolr/config/v3/CatalogGroup/x-schema.xml.

Adapt the additional fields and field types to the corresponding x-schema.xml and x-schema-field-types.xml files below WCDE-INSTALL/work space/search-config-ext/index/managed-solr/config to your HCL Commerce Workspace.

Read Section 3.4.5, "Adding New PARENT_PARTNUMBER Field to the Solr Index" [19] and Section 3.4.6, "Adding New CM_SEO_TOKEN Field to the Solr Index" [21] to learn more about the specific fields in detail.

3.4.5 Adding New PARENT_PARTNUMBER Field to the Solr Index

Searching HCL Commerce catalog assets in *CoreMedia Studio* is part of the seamless integration experience that *Content Cloud* brings to the table. Almost all the catalog assets are searchable in *Content Cloud* without any need of customization except for the catalog product asset which acts as a template for a group of items (or SKUs) that exhibit the same attributes.

This needs an extra property to explicitly define the hierarchical relationship between the product and its variants in order to make the variants also searchable in *Studio*. This subsection describes all the steps required to introduce the custom *CoreMedia Content Cloud* parent part number field which establishes the relationship between product and variant in WebSphere Commerce.

 Preprocessing data involves querying WebSphere commerce tables and creating a set of temporary tables to hold the data. The file Code\tsapp\xml\search\dataImport\v3\db2\CatalogEntry\wcdataimport-preprocess-parent-partnumber.xml in the customization package for the transaction server defines a custom preprocessing task for this. The file contains the new temporary table definition, database schema metadata, and a reference to the Java class used in the preprocessing steps for an Oracle database.

Simply copy the file to the corresponding location in your *HCL Commerce* RAD system. The workspace contains files for other databases which you can use similarly.

- 2. Extend the HCL Solr configuration files as follows:
 - a. Add the following new field to the HCL x-schema.xml file WCDE-IN STALL/workspace/search-config-ext/src/index/managedsolr/config/v3/CatalogEntry/x-schema.xml

```
<field name="parent partNumber ntk"
type="wc keywordTextLowerCase" indexed="true"
stored="true" multiValued="false"/>
```

- b. Extend the query select and the query from for parent part number using the wcdata-preprocess-x-finalbuild.xml file WCDE-INSTALL\work space\WC\xml\search\dataImport\v3\db2\Cata logEntry\wc-data-preprocess-x-finalbuild.xml.
- Rebuild the index as described in the HCL documentation at https://help.hcltechsw.com/commerce/9.0.0/search/tasks/tsdsearchbuildindex.html

WebSphere Commerce search contains a scheduler job (UpdateSearchIndex) to synchronize the catalog changes with the search index. The default update interval is 5 minutes. You can change this default value according to your needs in the WebSphere Commerce Administration Console.

3.4.6 Adding New CM_SEO_TOKEN Field to the Solr Index

Per default HCL behavior, you cannot distinguish the SEO keyword overridden by a store. If you have overridden the SEO keyword in the store, then you will get multiple SEO keywords in the response, without knowing which SEO keyword belongs to which store. To be able to distinguish the SEO keyword you need to extend the Solr field by adding the custom CM_SEO_TOKEN field in the Solr index. This custom CM_SEO_TOKEN field concatenates the store ID and the SEO keyword.

 Add a preprocessing file for CM_SEO_TOKEN field. The file Code\tsapp\xml\search\dataImport\v3\db2\CatalogEntry\wcdataimport-preprocess-cm-seo-token.xml in the CoreMedia HCL Commerce Workspace defines a custom preprocessing task for this. The file contains the new temporary table definition, database schema metadata and a reference to the Java class used in the preprocessing steps for an Oracle database.

Copy the file to the corresponding location in your *HCL Commerce* RAD system. The workspace contains files for other databases which you can use similarly.

- Extend the HCL Solr configuration files by including CM_SE0_TOKEN into the SQL statements as follows:
 - a. Add the following new field to the HCL x-schema.xml file WCDE-IN STALL/workspace/search-config-ext/src/index/managedsolr/config/v3/CatalogEntry/x-schema.xml

```
<field name="cm_seo_token_ntk"
type="wc_cmKeywordTextLowerCase" indexed="true"
stored="True" multiValued="true"/>
```

Example 3.2. New CM_SEO_TOKEN Solr field

- b. Extend the query select and the query from for parent part number using the wcdata-preprocess-x-finalbuild.xml file WCDE-INSTALL\work space\WC\xml\search\dataImport\v3\db2\Cata logEntry\wc-data-preprocess-x-finalbuild.xml.
- Rebuild the index as described in the HCL documentation at https://help.hcltechsw.com/commerce/9.0.0/search/tasks/tsdsearchbuildindex.html

WebSphere Commerce search contains a scheduler job (UpdateSearchIndex) that synchronizes catalog changes with the search index. The default update interval is 5 minutes. You can change the default value in the WebSphere Commerce Administration Console.

3.5 Extending REST Resources to BOD Mapping

NOTE

The BOD Mapping only needs to be extended if you do not make use of the search based REST handlers. Per default search based REST handlers are active and there is no need to apply the following.

In order to retrieve more detailed information from the REST handlers, the mapping of the REST resources to the Business Object Document [BOD] nouns has to be extended.

- To retrieve the SEO identifier of a product, create and edit the file WCDE-IN STALL/workspace/Rest/WebContent/WEB-INF/config/bodMap ping-ext/rest-productview-clientobjects.xml accordingly to the HCL Commerce Workspace archive.
- To retrieve the SEO identifier of a category, create and edit the file WCDE-IN STALL/workspace/Rest/WebContent/WEB-INF/config/bodMap ping-ext/rest-categoryview-clientobjects.xml accordingly to the HCL Commerce Workspace archive.

3.6 Configuring REST Handlers

Content Cloud requires additional REST handlers and some configuration of existing handlers.

Adding New REST Handlers

CoreMedia eCommerce API comes with additional REST handlers in order to make more data accessible and to provide additional data processing capabilities. The handler classes reside in the WebSphereCommerceServerExtensionsLogic module.

You have to add the following handlers:

LanguageMapHandler	The LanguageMapHandler returns a list of
	all available languages of the WebSphere Com-
	merce Server with its mapping on the internal lan-
	guage identifier which is used for certain REST calls.
StoreInfoHandler	The StoreInfoHandler returns the storeld
	and the catalog information of all available stores
	in the WebSphere Commerce Server.

In order to add the handlers proceed as follows:

- 1. Add the CoreMedia LiveContext library package to the Rest module in your commerce development workspace.
- Add the following fully qualified names of the handlers to the file WCDE-IN STALL/workspace/Rest/WebContent/WEB-INF/config/re sources-ext.properties accordingly to the HCL Commerce Workspace archive.
- Add a resource element for each handler to the file WCDE-INSTALL/work space/Rest/WebContent/WEB-INF/config/com.ibm.com merce.rest-ext/wc-rest-resourceconfig.xml accordingly to the HCL Commerce Workspace archive.
- 4. For the CachelnvalidationHandler add the file WCDE-INSTALL/work space/WC/xml/config/com.ibm.commerce.catalog-ext/wcquery-CoreMedia-LiveContext.tpl from the HCL Commerce Workspace archive. The file contains a database template to access HCL Commerce CACHEIVL table.
- 5. Adapt all dbtype properties to your target database.

3.7 Applying Changes to the Management Center

Studio integrates the Management Center into its GUI. For the integration do as follows:

 Add the file WCDE-INSTALL/workspace/LOBTools/WebContent/Core MediaManagementCenterWrapper.html from the HCL Commerce Workspace archive to the LOBTools module.

This file is used from *CoreMedia Studio* for displaying products, categories and e-Marketing Spots in the *HCL Commerce* Management Center. The wrapper uses the original HCL Management Center JSP files embedded and delegates deep links to the appropriate HCL functions.

3.8 Deploying the CoreMedia Fragment Connector

The CoreMedia Fragment Connector is the component that connects with CoreMedia CAE in order to integrate CoreMedia content fragments in store pages. In order to perform a fragment request, the LiveContextEnvironment has to be configured in the WCDE_installdir/workspace/crs-web/WebCon tent/WEBINF/web.xml configuration file, as described below.

Changing the web.xml file

There are different approaches to configure the loading mechanism for properties for the fragment connector. The LiveContextEnvironment can load its configuration directly from web.xml, from a properties file and from the STORECONF table. The default implementation is PropertiesBasedIBMLiveContextEnvir onmentFactory.

The PropertiesBasedIBMLiveContextEnvironmentFactory extends the IBMLiveContextEnvironmentFactory and in addition loads properties from a resource file on the classpath. If the resource file cannot be found - or the resource cannot be loaded, it will throw RuntimeExceptions. The location of the properties resource must be given in a servlet context parameter named liveContext.proper ties.location. In the first place this factory tries to get a parameter from STORECONF table, in the second place from the properties file and if not found as fallback from web.xml.

Other approaches are the following:

- The DefaultLiveContextEnvironmentFactory reads the connector properties directly as context parameters directly from the web.xml.
- The IBMLiveContextEnvironmentFactory extends the DefaultLive ContextEnvironmentFactory and can be configured via the STORECONF table. If properties are not available in the STORECONF table the factory reads directly from the web.xml configuration.

The fragment connector is the central component in the commerce-led integration scenario [see Chapter 6, *Commerce-led Integration Scenario* [53]]. Configure the fragment connector for example as follows:

 Add the LiveContextEnvironment configuration as shown in WCDE-IN STALL/workspace/crs-web/WebContent/WEB-INF/web.xml to the corresponding file in the HCL RAD workspace. 2. In the file WCDE-INSTALL/workspace/crs-web/WebContent/WEB-INF/coremedia-connector.properties configure at least the parameter com.coremedia.fragmentConnector.liveCaeHost with the host URL of your Content Application Engine (CAE). If you use a single commerce system that should be able to connect to both, preview and production CAE, you also need to set com.coremedia.fragmentConnector.previewCaeHost with the host URL of the preview CAE. In case you have a dedicated Staging commerce system with separate Production System, you only need to configure one CAE host, each. Find the meaning of all parameters in the list below.

com.coremedia.fragment- Connector.cookieDomain	The cookieDomain is used when a fragment request is created. All accessible cookies are copied and added to this request using the spe- cified cookie domain. This way it is ensured that the CAE session cookie is detected by the CAE and fragments can be rendered depending on the logged on user. The cookieDomain can contain multiple cookieDomains separated by comma.
<pre>com.coremedia.fragment- Connector.uncondition- alCookieNames</pre>	A fragment request promotes cookies from the commerce request to the CAE. However, this policy is overruled by other features [for example, the newPreviewSession URL parameter]. In the unconditionalCookieNames property you can specify cookies that are always to be passed with the fragment request. The value must be a comma separated list of cookie names.
com.coremedia.fragment- Connector.environment	The optional parameter is used to identify the HCL Commerce system that is requesting a fragment from a CAE. It may be used to serve different sites for each commerce system that is connected to a single CMS. The strategy for resolving this paramet- er is implemented in the class LiveCom textSiteResolver. The method find SiteFor (@NonNull FragmentParamet ers fragmentParameters) checks if the environment parameters has been passed as request matrix parameter. If set [for ex-

ample:site:Aurora], a lookup is made if a site with a matching name and locale exists. If no site is found with the given name, the default lookup strategy, implemented in findSiteFor (@Non Null String storeId, @NonNull

Locale locale) is used.

Customizing *HCL Commerce* 9.0 | Deploying the CoreMedia Fragment Connector

com.coremedia.fragment- Connector.liveCaeHost	The liveCaeHost identifies the Live CAE, to be precise, the Varnish, Apache or any other proxy in front of the Live CAE. Each request made by the fragment connector will be prefixed with the urlPrefix.
com.coremedia.fragment- Connector.previewCae- Host	The previewCaeHost identifies the Preview CAE, to be precise, the Varnish, Apache or any other proxy in front of the Preview CAE. Each request made by the fragment connector will be prefixed with the urlPrefix. The preview CaeHost is only required if you want a single <i>HCL Commerce</i> instance being able to access the preview CAE in case of <i>HCL Commerce</i> system preview and the live CAE in all other cases. Additionally, the preview mode can be invoked through an HTTP header. If you have a dedicated commerce instance for staging and separate production commerce system, you do not need to set this property. If this parameter is not set, the parameter liveCae Host will be used instead.
com.coremedia.fragment- Connector.urlPrefix	This prefix identifies the web application, the servlet context and the fragment handler to handle fragment requests. The default request mapping of all the handlers within <i>CoreMedia Blueprint</i> that are able to handle fragment requests start with service/fragment.
com.coremedia.wid- get.templates	Configures the template lookup path that is used when rendering CoreMedia Widget includes. Default is /Widgets-CoreMedia/com.core media.commerce.store.wid gets.CoreMediaContentWidget/im pl/templates/
<pre>com.coremedia.fragment- Connector.defaultLoc- ale</pre>	Every fragment request needs to contain the tuple (storeId, locale) because it is needed to map a request to the correct site. Using de faultLocale you can set a default that is used for every request that does not contain a custom locale. You will see how it is used later, when you see the IncludeTag in action.
com.coremedia.fragment- Connector.contextPro- vidersCSV	Every fragment request can be enriched with shop context specific data. It will be most likely user session related info, that is available in the <i>HCL</i> <i>Commerce</i> and can be provided to the backend

Customizing HCL Commerce 9.0 | Deploying the CoreMedia Fragment Connector

CAEviaa ContextProvider implementation. See Section 6.3, "Extending the Shop Context" [69] for details

- com.coremedia.fragment-The fragment connector will return error messages that occur in the CAE while rendering a fragment if Connector.isDevelopthe isDevelopment parameter is set to true. ment For production environments you should set this option to false. Errors are logged than but do not appear on the commerce page so that the end user will not recognize the errors.
- com.coremedia.fragment-Turn this flag to true if you want to disable the Connector.disabled fragment connector. Disabled means that the fragment connector always delivers an empty fragment. This property is not mandatory. If this property is not set, the default is false.

com.coremedia.fragment-The connection timeout in milliseconds used by Connector.connectionthe fragment connector; that is the time to establish a connection. A value of "0" means "infinite". Timeout Default is "10000".

com.coremedia.fragment-The socket read timeout in milliseconds used by Connector.socketthe fragment connector: that is the time to wait for a response after a connection has successfully Timeout. been established. A value of "0" means "infinite". Default is "30000".

com.coremedia.fragment-Maximum number of connections used by the Connector.connectionfragment connector. Default is 200.

com.coremedia.fragment- An optional access token that is sent along with all Connector.previewCaeAc- HTTP requests towards the CoreMedia preview CAE. Can be used by the CAE to authorize the access.

com.coremedia.fragment- An optional access token that is sent along with all HTTP requests towards the CoreMedia live CAE. Can be used by the CAE to authorize the access.

com.coremedia.fragment- If set to true the connector tries to prefetch frag-Connector.isPrefetchEn- ments for the current commerce page.

com.coremedia.fragment-Comma separated list of parameter names. If set. these parameters will be copied from the shop re-Connector.parameterInquest to the CAE fragment request. All other paracludeList. meter will be ignored. If set, this list has precedence

abled

cessTokenHeader

Connector liveCaeAc-

Customizing HCL Commerce 9.0 | Deploying the CoreMedia Fragment Connector

overcom.coremedia.fragmentConnect or.parameterExcludeList.

com.coremedia.fragment-Connector.parameterExcludeList
Comma separated list of parameter names. If set, all parameters but the configured ones will be copied from the shop request to the CAE fragment request. The property com.coremedia.frag mentConnector.parameterIncludeL ist has precedence.
3.9 Customizing HCL Commerce JSPs

When the CoreMedia Fragment Connector has been installed, the lc:include tag can be used in any JSPs of the Commerce Workspace to include content from the CoreMedia CMS. See Section 6.2.2, "The CoreMedia Include Tag" [61] for more details.

The HCL Commerce Workspace contains web content like JSP and JavaScript files in the crs-web/<STORE_NAME> folder. These files are mostly adapted versions of the JSP files of an original HCL RAD workspace. The CoreMedia customizations are highlighted with the following comment lines:

```
<!-- Begin CoreMedia XXX -->
CoreMedia snippet data
<!-- END CoreMedia XXX -->
```

The corresponding files in the HCL RAD workspace are in the workspace/crs-web/WebContent/<STORE NAME> folder.

If you have an Aurora RAD workspace without any customizations, you can copy the *HCL Commerce Workspace* archive content above it. Otherwise, you have to unzip the file and check for each file if you can copy the CoreMedia change into the corresponding file of your HCL RAD workspace.

How to adapt the files

Example

The CoreMedia archive contains custom Header.jsp and Footer.jsp files. These JSPs contain some include tags, highlighted with comments, to replace the default Aurora store header and footer with CoreMedia page grid placements. The placements contain the navigation and footer elements of the CAE. The original files are located in the folder workspace/crs-web/WebCon tent/<STORE NAME>/Widgets of the RAD workspace.

In addition, CoreMedia JavaScript and CSS that is used by the CAE must be included in the store front. To do so adapt the CoreMedia specific changes in WebCon tent/<STORE NAME>/Common/CommonJSToInclude.jspf.

3.10 Deploying the CoreMedia Widgets

The CoreMedia widgets are *HCL Commerce* Composer Widgets. You can use the *CoreMedia Content Widget* to add CoreMedia content fragments to your *HCL Commerce* pages and the *CoreMedia Asset Widget* to add product images to product detail pages.

Prerequisites

In order to use the CoreMedia widgets to embed CoreMedia fragments, the Fragment Connector needs to be deployed before executing these steps.

Register the Widget definition and subscribe your Store to it

See the HCL documentation at https://help.hcltechsw.com/commerce/9.0.0/data/concepts/cmlbatchoverview.html: for more details about data load.

- 1. Stop the HCL Commerce server in the HCL RAD environment.
- 2. Adapt the database settings in the *Data Load* environment configuration file [SAMPLEDATA-ZIP\workspace\DataLoad\dataload\common\wcdataload-env.xml] from the *CoreMedia Sample Data for HCL Commerce* Zip file to the settings of your WebSphere database.

You can retrieve your database settings from the HCL RAD environment configuration file WC/xml/config/wc-server.xml, at the following XML element:

```
<InstanceProperties>
<Database>
<DB>
```

For a DB2 database, the attribute schema in wc-dataload-env.xml corresponds to the attribute DBNode in wc-server-xml.

Find your store identifier in the HCL Management Center in *Store Management*. If you use the default HCL shop, the value is "Aurora".

3. Use the Data Load business object configuration files from the Sample Data for HCL Commerce ZIP file for registering the widget definition [workspace\Data Load\dataload\common\[store_name]\Widget\wc-loaderregisterWidgetdef.xml] and for subscribing the widget definition [work space\DataLoad\dataload\common\[store_name]\Widget\wcloader-subscribeWidgetdef.xml] where store_name is the store identifier of your store ["AuroraESite", for instance].

- 4. Use the CSV input files from the CoreMedia Sample Data for HCL Commerce ZIP file for registering the widget definition [workspace\DataLoad\dataload\com mon\[store_name]\Widget\registerWidgetdef.csv] and for subscribing the widget definition [workspace\DataLoad\dataload\com mon\[store_name]\Widget\subscribeWidgetdef.csv].
- 5. Configure the *Data Load* order configuration file [wc-dataload.xml]. The *Data Load* file has pointers to the environment settings file, the business object configuration file and the input file.

```
<?xml version="1.0" encoding="UTF-8"?>
< config:DataLoadConfiguration
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation=
     "http://www.ibm.com/xmlns/prod/commerce/foundation/config
       ../../../xml/config/xsd/wc-dataload.xsd"
   xmlns: config=
      "http://www.ibm.com/xmlns/prod/commerce/foundation/config">
 < config:DataLoadEnvironment configFile="wc-dataload-env.xml"/>
 < config:LoadOrder commitCount="100"
                    batchSize="1"
                    dataLoadMode="Replace">
   < config:property name="firstTwoLinesAreHeader" value="true"/>
   < config:property name="loadSEO" value="true"/>
   <!-- Configuration for the file to register a widget -->
   < config:LoadItem
       name="RegisterWidgetDef"
       businessObjectConfigFile=
          "wc-loader-registerWidgetdef.xml">
      < config:DataSourceLocation
         location="registerWidgetdef.csv"/>
   </ config:LoadItem>
   <!-- Configuration for the file to subscribe a store to a widget -->
   < config:LoadItem
       name="SubscribeWidgetDef"
       businessObjectConfigFile=
          "wc-loader-subscribeWidgetdef.xml">
      < config:DataSourceLocation
          location="subscribeWidgetdef.csv"/>
   </ config:LoadItem>
 </ config:LoadOrder>
</ config:DataLoadConfiguration>
```

Example 3.3. wc-dataload.xml

6. Run the Data Load utility command syntax with the dataload.bat tool which is located in workspace\bin of the RAD environment. Give the absolute path to the wcdataload.xml file. The call might look as follows: ..\bin\dataload.bat [path to your dataload]\wc-dataload.xml

Load the custom access control policies for the CoreMedia Widget

- 1. Stop the HCL Commerce server in the HCL RAD environment.
- Copy the custom access control policies file workspace/DataLoad/acp/com mon/CoreMediaContentDisplay.xml to the access control policies directory which is located in xml\policies\xml of the RAD environment.
- 3. Run the *ACP Load* utility with the *acpload.bat* tool which is located in work space\bin of the RAD environment. Give the absolute path to the acp-file name.xml file. The call might look as follows:

..\bin\acpload.bat [path to your acp dir]\acp-filename.xml

The ACP Load documentation can be found here: https://help.hcltechsw.com/com-merce/9.0.0/admin/refs/raxacpload.html.

NOTE

The acpload tool itself does not report any problems. So, check if the tool created two new XML files with the suffixes _xmltrans.xml and _idres.xml in ..\xml\policies\xml for each policy file. Also, look into ..\logs\acpload.log and ..\logs\messages.txt for errors.

Add the Widget UI to the Management Center app

1. Copy and merge the LOBTools folder content into the LOBTools folder of the HCL RAD workspace.

Copy the crs-web Folder and Apply JSP Customizations

Copy and merge the content of the crs-web/ folder of the *HCL Commerce Workspace* archive into the HCL RAD workspace folder crs-web/ as described in Section 3.9, "Customizing HCL Commerce JSPs" [30]

Using Placeholder Resolution for Asset URLs

If you have licensed CoreMedia Advanced Asset Management you can use placeholders for the CMS host and the store ID in your image URLs. Section 6.6.4.2, "Placeholder Resolution for Asset URLs" in *Blueprint Developer Manual* describes further details and how you enable placeholder resolution.

Refresh and Rebuild the workspace in Eclipse (RAD)

Now you have to refresh and rebuild the HCL workspace in the HCL RAD environment.

- 1. Refresh the projects in the HCL RAD system so that the new files are recognized:
 - a. Select the crs-web project and press F5
 - b. Select the WebSphereCommerceServerExtensionsLogic project and press $\mathsf{F5}$
 - c. Select the LOBTools project and press $\mathsf{F5}$
- 2. Rebuild the LOBTools:
 - a. Rebuild the LOBTools in order to apply the changes to the management Center application.

This steps might take some time.

Republish the HCL Commerce server workspace in order to apply the changes to the shop web application. In the server view (bottom left corner) right click on the server instance and select Publish from the context menu.

You have updated the Management Center tools and the development workspace and the *HCL Commerce* server has been restarted.

3.11 Setting up SEO URLs for CoreMedia Pages

HCL Commerce contains a default SEO-URL configuration for its shopping pages, such as product detail pages or category landing page. For a seamless integration of Core-Media content pages like CoreMedia article pages the SEO-URL configuration needs to be extended. The HCL Commerce Workspace archive comes with a SEO-URL configuration, which you can apply to your project HCL Commerce workspace.

The CoreMedia SEO-URL configuration is required for the usage of CoreMedia Content Display in your *HCL Commerce* environment.

As a prerequisite, SEO URLs require the custom access control policies, installed in Section 3.10, "Deploying the CoreMedia Widgets" [31].

In order to enable the CoreMedia SEO URLs do the following steps:

 Define the SEO pattern and its mapping for a given StoreName (Aurora or AuroraEsite, for instance). See the HCL documentation at https://help.hcltechsw.com/commerce/9.0.0/seositemap/concepts/csdSEOpatternfiles.html for more details about SEO configuration.

To do so, copy the SEO pattern file workspace/crs-web/WebCon tent/WEB-INF/xml/seo/stores/{StoreName}/SEOURLPat terns-CoreMedia.xml to your project workspace.

NOTE

For development, create a file .reload [text file] in the same directory and add this line: reloadinterval = 30. This will reload the SEO patterns file every 30 seconds.

2. Configure the handling of SEO Requests as follows:

Extend the existing Spring MVC views.xml within the custom stores web archive. The location of the file is crs-web/WEB-INF/spring/views.xml

<import resource="classpath:/WEB-INF/spring/widgets-views-ext.xml"/>

Example 3.4. Import the customized widgets views

Check if the copied JSP files already contain the parameter *externalSeoSeg-ment*:

The SEO pattern specifies that the path segment after /cm/ will be mapped to a JSP parameter *externalSeoSegment*. Make sure the parameter is actually recognized and prepared to be passed to the lc-include tag as $lc_externalRef$ parameter.

Otherwise, check the JSP files in the CoreMedia archive file and copy the settings to the JSPs in the HCL workspace.

4. Check SEO links

As defined in SEOURLPatterns-CoreMedia.xml, the URL pattern *Core-MediaContentURL* can be used from within the HCL wcf:url tag. You can find the implementation of URL generation for CoreMedia content with this tag in the JSP file WCDE-ZIP/workspace/crs-web/WebContent/Widgets-CoreMedia/com.coremedia.commerce.store.widgets.Core MediaContentWidget/impl/templates/Content.url.jsp.Check that this file is already included in your HCL workspace. Otherwise, copy it.

NOTE

In oder to adapt the predefined URL prefix "/cm" for SEO URLs for CoreMedia Content Pages to your needs, you need to customize

- the HCL Commerce SEO URL pattern for CoreMedia Content Pages
- the property wcs.link.cm-path-identifier in your Commerce Adapter deployment

3.12 Deploying the CoreMedia Catalog Data

The Sample archive file contains CoreMedia store data that can be used together with the CoreMedia CMS Blueprint demo data. The data can be imported via data load.

Importing Data via Data Load

See the HCL Commerce documentation https://help.hcltechsw.com/commerce/9.0.0/data/concepts/cmlbatchoverview.html for more details about data load.

- 1. Stop the HCL Commerce server in the HCL RAD environment.
- Adapt the database settings in the Data Load environment configuration files [SAMPLEDATA-ZIP\workspace\DataLoad\dataload\common\wcdataload-env[-<siteName>].xml] from the Sample archive Zip file to the settings of your WebSphere database.

You can retrieve your database settings from the HCL RAD environment configuration file WC/xml/config/wc-server.xml, at the following XML element:

```
<InstanceProperties>
<Database>
<DB>
```

 Use the Data Load utility to load the data for all sites. Give the absolute path to the wc-dataload.xml file, for example c:\lc-demo-data\work space\DataLoad\dataload\common\AuroraESite\wc-data load.xml.

4. Supporting HCL Commerce 9.1

There are two types of systems come with *HCL Commerce* 9.1, the new React-based store with elasticsearch-based search and a legacy JSP-based store with solr-based search.

NOTE

The customization for a legacy JSP-based store with solr-based search in *HCL Commerce* 9.1 is still compatible with the customization for *HCL Commerce* 9.0 [see also Chapter 3, *Customizing HCL Commerce* 9.0 [11]]. The workspace archive for version 9.0 can also be used for this legacy variant of version 9.1. Please note that this integration scenario requires a project-approval and is not supported by default.

The current support for *HCL Commerce* version 9.1 only applies to the headless scenario. The React-based storefront of the *HCL Commerce* 9.1 requires the CMS content to be provided via the *Headless Server*. There is consequently no need for a *CAE* application that delivers fragments to a storefront. Only in *CoreMedia Studio* the catalog tree from the *HCL Commerce* catalog is visible and *Studio* can be used to define additional content or navigation for your commerce system and to augment category and product pages.

Since the delivering of CMS content is done via the *Headless Server Studio* can show a JSON Preview for each page in the Emerald example site. That JSON can be taken as an example to build a frontend accordingly. [see also Figure 8.5, "Product in tab with JSON preview (HCL Commerce 9.1)" [99] and Figure 8.8, "Category in tab preview (HCL Commerce 9.1)" [100]].

The connection of *Headless Server* and *CoreMedia Studio* to a *HCL Commerce* 9.1 system uses the Commerce Hub and thus the Commerce Adapter. The configuration consists of two parts:

- Configuration of the Commerce Adapter to connect to a *HCL Commerce* 9.1 system is using the same commerce adapter basic configuration with an additional property wcs.search-profile-prefix [see also Section 5.1, "Configuring the Commerce Adapter" [41]] but note, there are some properties that are not used for a headless integration. All properties that are needed to build links will be ignored because links are built in the frontend in the headless scenario.
- Settings configuration in Studio references the Commerce Adapter endpoint, which Studio and Headless Server use to communicate via the Commerce Adapter with the

HCL Commerce 9.1 [see also Section 5.2, "Shop Configuration in Content Settings" [43]].

NOTE

For the headless scenario either with elasticsearch-based search or with solr-based search, there is no customization needed on the *HCL Commerce* side. Only standard REST handlers will be called and no search profile adjustment is required. There is no active code deployed to the *HCL Commerce* to fetch content. This needs to be done in the headless storefront client. For more information please refer to the *Headless Server* manual.

NOTE

The commerce-adapter-wcs supports HCL Commerce 9.1 since version 1.4.0.

i.

5. Connecting with an HCL Commerce Shop via Commerce Adapter

The connection of your *Blueprint* web applications [*Studio* or *CAE*] to a *HCL Commerce* system is configured on the Commerce Adapter side and on the CMS side. The configuration consists of two parts:

- Configuration of the Commerce Adapter to connect to a HCL Commerce system
- Settings configuration in *Studio*. It references the Commerce Adapter endpoint, which *Studio* and *CAE* use to indirectly communicate via the Commerce Adapter with the *HCL Commerce*.

NOTE

Prerequisite

Before connecting the CoreMedia system to the *HCL Commerce* system deploy first the CoreMedia extensions into your *HCL Commerce Workspace* as described in Chapter 3, *Customizing HCL Commerce 9.0* [11].

5.1 Configuring the Commerce Adapter

Configuring the Commerce Adapter

The physical connection to the *HCL Commerce Server* system is configured in the Commerce Adapter. The Commerce Adapter itself communicates via REST API calls with the *HCL Commerce Server* system.

The Commerce Adapter comes along with a set of configuration properties. For detailed documentation and defaults see Chapter 12, *Commerce Adapter Properties* [133].

The commerce-adapter-wcs provides Spring profiles for the different *HCL Commerce Server* versions that are supported. These profiles configure the suitable URLs that are required to connect to the *HCL Commerce Server*. To use these profiles, set the wcs.host property and activate the Spring profile wcs-[VERSION] when starting the adapter application.

Starting the Commerce Adapter

This guide describes how to build and run the commerce-adapter-wcs Docker container.

Prerequisites to be installed:

- Maven
- Docker
- Docker Compose (optional)

CoreMedia provides a Docker setup for the *HCL Commerce Connector*. It is part of a dedicated CoreMedia HCL Commerce Connector Contributions Repository.

After cloning the workspace, a coremedia/commerce-adapter-wcs Docker image can be build via mvn clean install command.

To run the commerce-adapter-wcs Docker container, the configuration properties for the adapter must be set [see above]. Spring Boot offers several ways to set the configuration properties, see Spring Boot Reference Guide - 24. Externalized Configuration. When starting the Docker container, this will probably lead to setting either environment variables [using the Docker option --env or --env-file] or mounting a configuration file [using the Docker option --volume].

The Docker container can be started with the command

```
docker run \
    --detach \
    --rm \
    --name commerce-adapter-wcs \
    --publish 44365:6565 \
    -publish 44381:8081 \
    [--env ...|--env-file ...|--volume] \
    coremedia/commerce-adapter-wcs:${ADAPTER VERSION}
```

To run the commerce-adapter-wcs Docker container with the CoreMedia CMCC Docker environment, add the commerce-adapter-wcs.yml compose file that is provided with the CoreMedia Blueprint Workspace to the COMPOSE_FILE variable in the Docker Compose .env file. Ensure that the environment variables that are passed to the Docker container are also defined in the .env file:

```
COMPOSE FILE=compose/default.yml:compose/commerce-adapter-wcs.yml WCS_HOST=...
```

The commerce-adapter-wcs container is started with the CoreMedia CMCC Docker environment when running

docker compose up --detach

Detailed information about how to set up the CoreMedia CMCC Docker environment can be found in Chapter 2, *Docker Setup* in *Deployment Manual*.

NOTE

For HCL Commerce 9.1, it is recommended to use the following search profile prefix:

- HCL for the headless integration with elasticsearch-based search
- IBM for the headless integration with solr-based search

For earlier *HCL Commerce* versions, it is recommended to use the default search profile prefix CoreMedia.

5.2 Shop Configuration in Content Settings

The store specific properties that logically define a shop instance are part of the content settings. They configure the Commerce Adapter endpoint, which storeld should be used, which catalog, the currency and other shop related settings.

Refer to the Javadoc of the class com.coremedia.blueprint.base.livecontext.client.settings.CommerceSettings for further details.

Each site can have one single shop configuration (see the Blueprint site concept to learn what a site is). That means only shop items from exactly that shop instance (with a particular view to the product catalog) can be interwoven to the content elements of that site. In the example settings there is a LiveContext settings content item linked with the root channel. This is the perfect place to make these settings.g

The following store specific settings can be configured below the struct property named

commerce: Name Type Description Example Required

endpoint	String Property	Host and Port of the Com- merce Adapter.	wcs-com- merce-ad- apter:6565	true (if end- pointName is not set)
endpoint Name	String Property	The endpoint name to lookup the Spring gRPC service con- figuration .	WCS	true (if end- point is not set)
locale	String Property	The ISO locale code for the connected Catalog. This over- writes the Site locale. It is only needed if the CoreMedia Site locale differs from the Shop locale and if you need the ex- act Shop locale to access the catalog.	en-US	false
currency	String Property	The displayed currency for all product prices.	USD	false. If not set, the cur- rency will be retrieved

Name	Туре	Description	Example	Required
				from the site locale.
storeConfig	Struct Property	Struct property containing store configuration.		true
storeCon fig.id	String Property	Store id that is used to access the store. If the StoreIn foHandler is deployed on the HCL Commerce Server side, it can be retrieved auto- matically by mapping an exist- ing store name.	700012345678	false
storeCon fig.name	String Property	Store name that is used to ac- cess the store. If the Store InfoHandler is deployed on the <i>HCL Commerce Server</i> side, the name is used to re- trieve the store id.	AuroraESite	true
catalogCon fig	Struct Property	Struct property containing catalog configuration. In a multi-catalog scenario addi- tional catalog configurations can be added via the addi tionalCatalogCon figs configuration. The catalog behind the catalog Config entry is treated as default catalog then.		true
catalogCon fig.id	String Property	Catalog id that is used to ac- cess the catalog. If not set, the ID of the default catalog is used.	300012345678	false
catalogCon fig.name	String Property	Catalog name that is used to display a catalog name (e.g in the <i>Studio</i> library). If not set, the ID of the default catalog is used. setting.	AuroraESite- SalesCatalog	false

Name	Туре	Description	Example	Required
catalogCon fig.alias	String Property	Catalog alias that is used in content to store links to cata- log items. The alias <i>cata-</i> <i>log</i> is reserved and used for the default catalog. If not set, the string <i>catalog</i> is used.	master	false
additionalC atalogCon figs	Struct List	List of additional catalog con- figurations used for multi- catalog scenario. Each entry should provide the properties described earlier for the catalogConfig entry. The property alias and at least one of id or name must be defined.		
customEnti tyParams	Struct Property	Site specific custom entity parameters, which are at- tached to the communication with the commerce adapter. See Section 5.4, "Configuring Custom Entity Paramet- ers" [51] for more information.		false. If not set, no site specific cus- tom entities will be used.

Table 5.1. Livecontext settings

NOTE

Be aware, that the locale is also part of each shop context. It is defined by the locale of the site. That means all localized product texts and descriptions have the same language as the site in which they are included and one specific currency.

Configuring Multiple Catalogs

By default, *CoreMedia Studio* only shows the default catalog of the *HCL Commerce* system. However, you can configure multiple catalogs which can be defined in *Studio* via a struct list property additionalCatalogConfigs below the commerce struct. Proceed as follows:

- Open the LiveContext Settings content in Sites/<Site Name>/<Locale Country>/<Locale Language>/Options/Set tings (for example Sites/Aurora Augmentation/United States/English/Options/Settings).
- 2. If it does not exist, add a Struct List property named *additionalCatalogConfigs* below the commerce Struct to the *Settings* field.
- 3. For each catalog add a Struct item to the Struct List property additionalCata logConfigs. Each entry should at least define an alias and an id or name property. The property alias is used to link to catalog items internally and shouldn't be changed anymore. The property id corresponds to the id of the catalog in the commerce system. The property name corresponds to the name of the catalog in the commerce system.

		8							
Default Catalog (AuroraESite)		* Type \sim	Store \checkmark	* Unique ID	* Code	* Name			
	0		Extended Sites Catalog Asset Store	30744573456 16676719	Extended Sites Catalog Asset Store Consumer Direct	Aurora consumer direct sample data			
		0 of 1 selected				•			

Figure 5.1. Catalog code in commerce system

For backward compatibility, the default catalog needs to have the alias "catalog".

	livecontext.policy.commerce-product-links	8	Boolean
	livecontext.policy.commerce-category-links	8	Boolean
	livecontext.policy.commerce-page-links	¥	Boolean

Figure 5.2. Catalog settings

Name	Туре	Value
The alias for the catalog. You can freely define a name which must be alphanumeric including '_' and '-'. Only the default catalog requires the alias "catalog".	String	The HCL Commerce code of the catalog

Table 5.2. Catalog aliases

CAUTION

The defined aliases are then used as part of internal IDs which are persisted in the system.

Therefore, choose the alias wisely before the multi-catalog feature is used. Changing the alias afterward would require some cumbersome data migration.

Enabling Dynamic Pricing

Dynamic price rendering is disabled by default. If this feature is not used on *HCL Commerce* side, then it is not necessary to turn it on on CMS side. It avoids an additional call to *HCL Commerce* that is not needed in such a scenario.

But if you use personalized price rules in *HCL Commerce* then it is necessary to switch this feature on.

Name	Туре	Description	Example	Required
config.id	String Property	The configuration ID defined in Spring configura- tion	myStore	true
dynamicPricing.en abled	Boolean Property	Personalized product prices en- abled	true	false

Table 5.3. Currency configuration

Please see Section 5.1, "Configuring the Commerce Adapter" [41] to get the information how the dynamic prices can be switched on on *HCL Commerce* side.

5.3 Check if everything is working

Prerequisites

- The CoreMedia Content Cloud infrastructure has been deployed and is running.
- The HCL Commerce Workspace has been applied to the HCL Commerce Workspace and the HCL Commerce server is running.
- The *HCL Commerce* sandbox is accessible from CoreMedia Studio and the Commerce Adapter servers.
- The CoreMedia Preview CAE and Live CAE are accessible from the HCL Commerce server.

Check the Studio - HCL Commerce REST Connection

- 1. Open *Studio*, select the "Aurora Augmentation English [United States]" site, open the Library. If necessary, switch the Library to browse Mode.
- 2. In the repository tree view, locate a node named *AuroraESite*. This is the entry point to browse the connected *HCL Commerce* product catalog.
- 3. Browse the catalog in studio and check if everything works as expected. Section 8.1, "Catalog View in CoreMedia Studio Library" [96] describes what it looks like.

If errors occur:

- Check the Studio log and the Commerce Adapter log for errors.
- Check in *CoreMedia Studio* if the "LiveContextSettings" are configured correctly, see Section 5.2, "Shop Configuration in Content Settings" [43].
- Check if the REST connector is configured correctly [see Section 5.1, "Configuring the Commerce Adapter" [41]]. Check for example, if the deployment property wcs.host is configured correctly.

Check Studio - HCL Commerce Preview Integration

1. Open the Homepage of the "Aurora Augmentation - English [United States]" site in Studio

The HCL Commerce shop page should be displayed in the preview panel.

2. Repeat step 1 for Products and Categories.

If errors occur:

- Check the Studio log, the Preview CAE log and the Commerce Adapter log for errors.
- Check if wcs.link.storefront-url is configured correctly for Commerce Adapter.

Check Fragment Connector

1. Open the Aurora Augmentation - English [United States] homepage and check if CoreMedia Demo content is displayed.

If errors occurred or no CoreMedia Content is displayed

- Check for errors in the *HCL Commerce* log and the Preview *CAE* log and the Commerce Adapter log.
- Check in Management Center if the homepage has content slots containing CoreMedia Content Widgets or if render templates contain a lcinclude tag.

Connecting with an HCL Commerce Shop via Commerce Adapter | Configuring Custom Entity Parameters

5.4 Configuring Custom Entity Parameters

Custom entity parameters can be used to transport additional information from the client to the commerce adapter.

Let's say you want to transmit the environment type [Dev, UAT, Prod] of your client with every request. This way you want to resolve certain host names on the adapter side for different environments. Out of the box there is no dedicated field "environment" available in the EntityParams, which are sent along with every request from the client to the commerce system. The custom entity parameters enable you to provide this information to the adapter side without API changes. You can do this by simple configuration.

Example:

This example shows a configuration for an *environment* entity parameter:

Adapter Configuration

Configure on the adapter side metadata.custom-entity-paramnames=environment to tell the connected clients, to send the custom parameter named "environment" alongside with every client request.

Client Configuration

Configure a global variable on the client side, using the property com merce.hub.data.customEntityParams.Simplyadd the name of the variable to the property name:

```
commerce.hub.data.customEntityParams.environment=UAT
```

You can also configure custom entity params in *Studio* via commerce settings. This way, it is possible to transmit site specific environment parameters to the commerce adapter.

```
commerce (Struct)
customEntityParams (Struct)
environment=UAT (String)
```

Connecting with an HCL Commerce Shop via Commerce Adapter | Configuring Custom Entity Parameters

NOTE

If the same parameter is defined via property and via *Studio* commerce settings, the site specific commerce settings configuration has precedence over the global property based configuration.

i.

6. Commerce-led Integration Scenario

In the commerce-led integration scenario the commerce system delivers content to the customer. The shop pages are augmented with fragment content from the CoreMedia system.

This chapter describes how you include the content from the CMS into shop pages. Have also a look into Section 8.5, "Augmenting Commerce Content" [108] and Chapter 6, *Working with Product Catalogs* in *Studio User Manual* for more details about the *Studio* usage for eCommerce.

- Section 6.1, "Commerce-led Scenario Overview" [54] gives an overview over the request flow in the commerce-led integration scenario.
- Section 6.2, "Adding CMS Fragments to Shop Pages" [56] describes how you can add fragments to the commerce system via the CoreMedia widgets and the lc:in clude tag and how you can augment shop pages in *Studio*.
- Section 6.3, "Extending the Shop Context" [69] describes how you extend the shop context that is delivered to the CMS.
- Section 6.4, "Solutions for the Same-Origin Policy Problem" [72] describes how the same-origin policy problem has been solved for the CoreMedia solution.
- Section 6.5, "Caching In Commerce-Led Scenario" [75] describes the caching in the commerce-led scenario.
- Section 6.6, "Prefetch Fragments to Minimize CMS Requests" [80] describes how to prefetch fragments in the commerce-led scenario.

NOTE

This chapter does not apply to *HCL Commerce* 9.1. More information on the Headless Integration Scenario can be found in Chapter 4, *Supporting HCL Commerce* 9.1 [38].

6.1 Commerce-led Scenario Overview

Figure 6.1. Commerce-led Architecture Overview

Figure 6.1, "Commerce-led Architecture Overview" [54] shows the commerce-led integration scenario where the CoreMedia *CAE* operates behind the commerce server for all page request. Moreover, you can see two kinds of requests. While the left side shows HTTP page requests to the commerce server, that include fragments delivered by the *CAE*, the right side shows resource or Ajax requests directly redirected by the one virtual host in front of both servers to the *CAE*.

A typical flow of requests through a commerce-led system is as follows:

Figure 6.2. Commerce-led Request Flow

- 1. A user requests a product detail page that is received by the virtual host.
- 2. The virtual host identifies the request as a commerce request and forwards it to the commerce server.
- 3. Part of the requested Product Detail Page (PDP) is a CMS content fragment. Hence, the commerce system requests the fragment from the *CAE*.
- 4. The resulting HTML page flows back to the user's browsers. Because the page contains dynamic CAE fragments which have to be fetched via Ajax, the browser triggers the corresponding request against the virtual host.
- 5. As this is a CAE request, the virtual host forwards it directly to the CAE.

From the point of view of the user all requests are sent to exactly one system, represented by the one virtual host that forwards the requests accordingly. That leads to the same-origin policy problem. Solutions for this are presented in section Section 6.4, "Solutions for the Same-Origin Policy Problem" [72].

6.2 Adding CMS Fragments to Shop Pages

A pure eCommerce system is focused on the more transactional aspects of the buying process. To create a more engaging user experience you can augment the catalog pages with editorial content from the CMS. This includes, articles, images or videos.

Figure 6.3. Various Shop Pages with CMS Fragments

There are two types of shop pages that can be extended by CoreMedia Content Cloud:

- Catalog Pages that are part of the catalog hierarchy, like a Category Overview or Landing Page and a Product Detail Page (PDP). They are extended by Augmented Categories and Augmented Products in the CMS.
- Other Pages that are not located in the catalog hierarchy. For example, all subordinate shop pages like "Contact Us", "Log On", "Checkout", "Register" or "Search Result", which also belong to a shop but don't have a category or a product connected with.

Even the homepage and other special topic pages belong to this type. These pages are extended by Augmented Pages in the CMS.

Types of augmentable pages In addition, you can show complete CMS pages in the context of the commerce system. That page type is called **Content Pages**.

The basis for augmentation is the use of the *CoreMedia Content Widget* or the lc:in clude tag in the commerce system.

On the commerce side, add the *CoreMedia Content Widget* to the commerce page layouts or write the lc:include tag directly into a shop template. The value of the placement property corresponds to the placement name within a CMS-side page layout. Technically, the *CoreMedia Content Widget* uses also the lc:include tag internally. See Section 6.2.1, "CoreMedia Widgets" [57] and Section 6.2.2, "The CoreMedia Include Tag" [61] for details.

When you have prepared the shop-side with such content slots (either as *CoreMedia Content Widget* or directly with lc:include tags in shop templates), and the commerce system is properly connected with the CMS systems, you can now start augmenting shop pages in *Studio*.

Section 8.5, "Augmenting Commerce Content" [108] describes the procedure.

6.2.1 CoreMedia Widgets

On the *HCL Commerce* side it is necessary to define slots where the CMS content can be displayed. This is normally done by adding the *CoreMedia Content Widgets* to an *HCL Commerce* page layout.

In other cases, where a widget cannot be used, it can also be achieved by directly adding an lc:include tag into a JSP within the *HCL Commerce* workspace. This is typically done in advance during the project phase. Later, editors will only deal with Augmented Categories and Augmented Pages that they can edit and preview via *CoreMedia Studio*.

The content that is shown in the *CoreMedia Content Widget* is taken from a placement in the augmented content item, whose name corresponds with the name set in the widget. See Figure 6.4, "Connection via placement name" [58] for an example. Note, that the name of the placement shown in the Studio form is only a localized label. The name in the *Content Widget* must match with the technical name in the page grid definition. If the widget defines no placement, the full page grid is taken. The augmentation process

Figure 6.4. Connection via placement name

The CoreMedia widgets are *HCL Commerce Composer Widgets* that display content or assets from the CMS on any page managed through the *HCL Commerce Composer*. After the CoreMedia widgets have been deployed on the commerce side [see Section 3.10, "Deploying the CoreMedia Widgets" [31]], two CoreMedia widgets are available in the *HCL Commerce Composer*.

- CoreMedia Content Widget

Figure 6.5. CoreMedia Widgets in Commerce Composer

Technically, the CoreMedia Widgets use the lc:include. See Section 6.2.2, "The CoreMedia Include Tag" [61] for a description.

The CoreMedia Content Widget

You can use the Content Widget like any other Commerce Composer Widget. It has the following configuration options:

Option	Description
Widget name	The widget name.
CoreMedia Placement Name	The name of the placement as defined in CoreMedia CMS. Content on page grids in CoreMedia are defined through so called placements. Each place- ment is associated with a specific position of the page grid through its name. Using CoreMedia Studio the editor can add content to the placement which

Option	Description
	will be shown at the associated position of the page grid and subsequently in the layout of this CoreMedia Content Widget.
CoreMedia View Name	The view of the placement as defined in CoreMedia CMS. Each placement can be rendered with a specific view which needs to be predefined to handle the content in a placement.

Table 6.1. CoreMedia Content Widget configuration options

The CoreMedia Product Asset Widget

NOTE

The Product Asset Widget is part of the *CoreMedia Advanced Asset Management* module described in Section 6.6, "Advanced Asset Management" in *Blueprint Developer Manual*. This module requires a separate license.

You can use the *CoreMedia Product Asset Widget* like any other *Commerce Composer Widget*. It has the following configuration option:

Option	Description
Display Pictures and Videos	If checked, a picture gallery is rendered from CMS pictures and videos that are associated with the product.
Orientation	The orientation of the pictures (only relevant if pictures are included). The possible values are <i>Square</i> and <i>Portrait</i>
Include Downloads	If checked, an <i>Additional Downloads</i> list is rendered from CMS <i>Download</i> content item that are associated with the product.

Table 6.2. CoreMedia Product Asset Widget configuration options

6.2.2 The CoreMedia Include Tag

Behind the scenes of the *CoreMedia Content Widget* works the CoreMedia lc:include tag. You may also use it in your own JSP templates to embed CoreMedia content on the commerce side. In general it is used like this:

```
<%@ taglib prefix="lc" uri="http://www.coremedia.com/2014/livecontext-2" %>
<lc:include
storeId="${WCParam.storeId}"
locale="${WCParam.locale}"
catalogId="${WCParam.cotalogId}"
productId="${WCParam.productId}"
categoryId="${WCParam.categoryId}"
placement="${param.placement}"
view="${param.view}"
externalRef="${WCParam.externalRef}"
exposeErrors="${lot empty WCParam.categoryId}"
httpStatusVar="fragmentHttpStatus"/>
```

All parameters are described in the next two sections.

Include Tag Reference

The tag attributes have the following meaning:

Parameter	Description
storeId, locale	These attributes are mandatory. They are used in the CAE to identify the site that provides the requested fragment.
catalogId	In a multi-catalog scenario this attribute is mandatory. It is used in the CAE to identify the catalog context for rendering the requested fragment.
productId,category- Id	These attributes are used in the CAE to find the context which will be used for rendering the requested fragment. Both parameters should not be set at the same time since depending on the attributes set for the include tag, different handlers are invoked: If the <i>categoryId</i> is set, Category FragmentHandler will be used to generate the fragment HTML. If the <i>productId</i> is set, ProductFragmentHandler will be used to generate the fragment HTML.
pageId	This parameter is optional. Usually, the page ID is computed from the reques- ted URL (the last token in the URL path without a file extension). If you set the parameter, the automatically generated value is overwritten. On the Blueprint side an <i>Augmented Page</i> will be retrieved to serve the fragment HTML. The transmitted page ID parameter must match the <i>External Page ID</i>

Commerce-led Integration Scenario | The CoreMedia Include Tag

Parameter	Description	
	of the <i>Augmented Page</i> . You might use the parameter, for example, in order to have one CoreMedia page to deliver the same content to different shop pages.	
placement	This attribute defines the name of a placement in the page grid of the reques- ted context. In the example for the header fragment, the "header" placement was used. If you do not want to render a certain placement but a view of the whole context [generally a CMChannel], you may omit it. If the view attribute isn't set, the "main" placement will be used as default instead. This attribute can be combined with the <i>externalRef</i> attribute. In this case the placement will be rendered for a specific CMChannel, so the external refer- ence must point to a CMChannel instance.	
view	The attribute "view" defines the name of the CMS view which will render the fragment. Such view templates must exist on the CMS side. There are several views prepared in the Blueprint: metadata (to render the HTML title and metadata), <i>externalHead</i> (to render parts of the HTML header like CSS and JavaScripts that are needed in CMS fragments), <i>externalFooter</i> (is also mostly used for loading scripts) and <i>asAssets</i> (that can render the <i>CoreMedia Product Asset Widget</i>). If you omit the view, the default view will be used. In such cases you have either the <i>placement</i> or the whole page grid of a CoreMedia page is rendered.	
externalRef	This attribute is used in the CAE to find content. Several formats are supported here as described in the next section. The attribute can be used in combination with the <i>view</i> and/or <i>parameter</i> attribute.	
parameter	This attribute is optional and may be used to apply a request attribute to the CAE request. The request attribute is stored using the constant Fragment PageHandler.PARAMETER_REQUEST_ATTRIBUTE. The value may be read from a triggered web flow, for example, to pass a redirect URL back to the commerce system once the flow is finished. The attribute also supports values to be passed in JSON format [using single quotes only], for example parameter="{ 'test':'some value', 'value':123}". The key/values pairs are available in the FragmentParameters object and may be accessed using the get ParameterValue (String key) method. Other additional values, like information about the request context that is build when the commerce system requests the fragment information from the CAE [see next section].	

Commerce-led Integration Scenario | The CoreMedia Include Tag

Parameter	Description
var	This attribute is optional. If set, the parsed output of the CAE is not written in the parsed output stream but in a page attribute named like the <i>var</i> parameter value. This allows you, for example, to replace or transform parts of the CAE result or, if empty, to render a different output.
exposeErrors	This attribute is optional. If set to true, the tag will expose any errors that occur during the interaction with the CMS. These errors are then directly written to the response. Thus, the commerce system has the ability to handle the errors, to show an error page, for instance.
httpStatusVar	This attribute is optional. If set, the HTTTP status code of the fragment request is set into a page attribute named like the <i>httpStatusVar</i> parameter value. This allows you, for example, to react on the result code, for example, set the fragment as uncacheable in the caching layer of your commerce system.

Table 6.3. Attributes of the Include tag

External References

Any linkable CoreMedia content can be included as a fragment by specifying a value for the externalRef attribute. The value of the attribute is applied to the first Extern alReferenceResolver predicate that is applicable for the externalRef value. The Spring list externalReferenceResolvers which contains the supported ExternalReferenceResolvers is injected to the ExternalRef FragmentHandler. This section shows the supported formats that are applicable for the existing resolvers.

The following table shows an overview about the possible values for the $\verb+externalRef$ attribute.

Value Type	Example	Description
Content ID	cm-coremedia:///cap/content/4712	Includes the content with the given cap id as fragment. The root channel of the corresponding site will be used as context.
Numeric Content ID	cm-4712	Works the same way like the content ID include, only with the numeric content ID.
Absolute Content Path	cm-path!!Themes!ba- sic!img!icons!ico_rte_link.png	Includes the content with the given abso- lute path. All exclamation marks ('!') after

Value Type	Example	Description
		the prefix 'cm-path!' will be mapped to slashes ['/'] to provide a valid absolute CMS path. The given path may not contain 'Sites' (referencing content of a different site is not allowed). The <i>storeId</i> and <i>locale</i> parameter are still mandatory for this case.
Relative Content Path	cm-path!actions!Login	Includes the content with the given path treated as a relative path from the site's root folder. All exclamation marks ['!'] after the prefix 'cm-path!' will be mapped to slashes ['/'] to provide a valid relative CMS path. The given path may not contain '' [going up in the hierarchy]. The site is determined through the <i>storeId</i> and <i>locale</i> parameter.
Numeric Context and Content ID	cm-3456-6780	The prefix is the numeric content ID of the context to be rendered. The suffix is the numeric content ID of the content to be rendered with the given context.
Segment Path	cm-segmentpath:!corporate!on-the-table	The actual value (excl. the format prefix cm-segmentpath:) denotes a seg- ment sequence, separated by exclama- tion marks. The segments are matched against the values of the segment properties of the content. The very last segment denotes the actual content. The other segments denote the navigation hierarchy which determines the context of the content. The example value refer- ences a linkable content with the segment on-the-table in the context of a channel corporate (which is appar- ently the root channel, since it consists of a single segment). The context and the content must fulfill the Blueprint's context relationship, otherwise the request is handled as invalid.

Commerce-led Integration Scenario | The CoreMedia Include Tag

Value Type	Example	Description
		Segment Path external references are re- solved by querying the Solr search engine. The <i>CAE Feeder</i> must be running for up- to-date results.
Search Term cm-searchterm:summer	cm-searchterm:summer	Includes the content that contains the given search term (specified after the prefix cm-searchterm:). This resolv- er is typically used to resolve search landing pages. By default, contents of type CMChannel below the segment path <root segment="">/livecon text-search-landing-pages are checked if their keywords search engine index field contains the term. Matching is case-insensitive by default and can be customized by using a differ- ent search engine field or field type. The value of the segment path which is used to identify the SLP channel is configured with the property livecon text.slp.segmentPath.</root>
	Content type and search engine field can be configured with Spring properties searchTermExternalReferen ceResolver.contentType and searchTermExternalReferen ceResolver.field, respectively. The segment path is configured as relative path after the root segment. The con- figured segment path value must not start with a slash.	
	Search term lookup is cached, by default for 60 seconds. You can configure the cache time in seconds with Spring prop- erty cache.timeout- seconds.com.coremedia.live context.fragment.resolv er.SearchTermExternalRefer enceResolver and the maximum number of cached search term lookups with cache.capacit	
Value Type	Example	Description
------------	---------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------
		ies.com.coremedia.livecon text.fragment.resolv er.SearchTermExternalRefer enceResolver (defaults to 10000). Search Term external references are re- solved by querying the Solr search engine. The <i>CAE Feeder</i> must be running for up- to-date results.

Table 6.4. Supported usages of the externalRef attribute

Finding Handlers

You can control the behavior of the include tag by providing different sets of attributes. Depending on the used attributes, different handlers are invoked to generate the HTML.

The CoreMedia lc:include tag requests data from the CAE via HTTP. Each attribute value of the include tag is passed as path or matrix parameter to the FragmentPage Handler. In order to find the matching handler, the FragmentPageHandler class calls the include method of all fragment handler classes defined in the file livecontext-fragment.xml. The first handler that returns "true" generates the HTML. Example 6.1, "Default fragment handler order" [66] shows the default order:

```
<util:list id="fragmentHandlers"
value-type="com.coremedia.livecontext.fragment.FragmentHandler">
<description>This list contains all handlers that are used for fragment
calls.</description>
<ref bean="externalRefFragmentHandler" />
<ref bean="productFragmentHandler" />
<ref bean="roductFragmentHandler" />
<ref bean="categoryFragmentHandler" />
</util:list>
```

Example 6.1. Default fragment handler order

If the handlers are in the default order, then the table shows which handler is used depending on the attributes set. An "x" means that the attribute is set, a "-" means that the attribute is not allowed to be set and no entry means that it does not matter if something is set. For more details, have a look into the handler classes.

External	Page ID	Category ID	Product ID	Used Handler
Reference				

Х

ExternalRefFragmentHandler

External Reference	Page ID	Category ID	Product ID	Used Handler
-	х	-	-	ExternalPageFragmentHand ler
-			х	ProductFragmentHandler
-		х	-	CategoryFragmentHandler

Table 6.5. Fragment handler usage

NOTE

The parameters category id and product id may be treated as technical id or as external id. It is recommended to work with external ids if possible. If the commerce system cannot pass external ids into the fragment parameters because only technical ids are available, this behaviour must be configured on the commerce adapter side. The property metadata.additional-metadata.allow-tech-ids=true has to be set for the commerce adapter, if you want to use technical ids in the fragment connector.

For customers using *HCL Commerce* the property metadata.additionalmetadata.allow-tech-ids=true is set by default.

Fragment Request Context

In addition to the passed request parameters, a context is build by the registered ContextProvider implementations that are part of the commerce workspace. The context provider passes context information as header attributes to the CAE. For more details see Section 6.3, "Extending the Shop Context" [69].

CMS Error Handling

Since the CoreMedia include tag requests data from the CAE via HTTP, errors can occur. The error handling can be controlled by different parameters. If the *com.coremedia.fragmentConnector.isDevelopment* property [see Section 3.8, "Deploying the CoreMedia Fragment Connector" [25]] is set to true, the include tag will embed occurring error messages as strings into the page output. You may not want to see such information on the live side, thus the flag can be set to false and all output will be suppressed (the errors are only visible in the log).

This behavior is sufficient for providing additional (possibly optional) information on a page, a banner or teaser, for instance. But if the requested content is the major content of a page, then it is not desirable to deliver a mainly empty page. In such a case the commerce system should be able to handle the error situation and answer in an appropriate form. That could be, for example, a 404 error page.

For this purpose the *exposeErrors* parameter was introduced to the include tag. If this parameter is set to true, the tag will expose any error that occurs during the interaction with the CMS. These errors are directly written to the response. Sending a response with an error status code (404, for instance) requires that still nothing has been written to the Response object. Therefore, this flag should only be set on the include tag if rendered early enough before any other response code has been set.

In the *HCL Commerce* reference workspace the usage of the *exposeErrors* parameter is demonstrated in the CommonJSToInclude.jspf template. The template is executed on every page request and renders, among other things, the HTML head section of a page. The first occurrence of the include tag is used to do the error handling.

Since the template is executed for all shop pages the flag must be set depending on the target page. If it's a content centered page (it has, for example, a *cm* parameter), then the parameter would be set to true, in case of a category or product detail page probably not.

```
exposeErrors="${not empty WCParam.externalRef && empty WCParam.productId &&
empty WCParam.categoryId}"
```

Another possibility to handle failed fragment requests is the usage of the *httpStatus*-*Var* parameter. If this parameter is set, the include tag will write the HTTP status code of the fragment request into a JSP attribute/variable. You can then add JSP code to react on specific result codes and for example disable caching of this fragment in the commerce cache.

```
<lpre><lc:include ...
httpStatusVar="status"/>
...
<c:if test="${not empty status && status >= 400}">
... // error handling
</c:if>
```

6.3 Extending the Shop Context

To render personalized or contextualized info in content areas it is important to have relevant shop context info available during CAE rendering. It will be most likely user session related info, that is available in the Commerce system only and must now be provided to the backend CAE. Examples are the user id of a logged in user, gender, the date the user was logged in the last time or the names of the customer segment groups the user belongs to, up to the info which campaign should be applied. Of course these are just examples and you can imagine much more. So it is important to have a framework in order to extend the transferred shop context information flexibly.

The relevant shop context will be transmitted to the CoreMedia CAE automatically as HTTP header parameters and can there be accessed for using it as "personalization filter". It is a big advantage of the dynamic rendering of a CoreMedia CAE that you can easily process this information at rendering time.

The transmission of the context will be done automatically. You do not have to take care of it. On the one end, at the commerce system, there is a context provider framework where the context info is gathered, packaged and then automatically transferred to the backend CAE. A default context provider is active and can be replaced or supplemented by your own ContextProvider implementation.

Implement a custom ContextProvider

To extend the shop context you have to supply implementations of the ContextPro vider interface. The ContextProvider interface demands the implementation of a single method.

```
package com.coremedia.livecontext.connector.context;
import javax.servlet.http.HttpServletRequest;
public interface ContextProvider {
    /**
    * Add values to the given context.
    * @param contextBuilder the contextBuilder - the means to add entries to
    the entry
    * @param request - the current request, from which e.g. the session can
    be retrieved
    * @param environment - an environment, not further specified
    */oid addToContext(ContextBuilder contextBuilder, HttpServletRequest request,
    Object environment);
}
```

Example 6.2. ContextProvider interface method

Such implementations of the ContextProvider interface must be provided with the *HCL Commerce* workspace. This is typically done below the WebSphereCom merceServerExtensionsLogic directory of the your *HCL Commerce* project workspace. Such context provider implementations will use the *HCL Commerce* API to gather information from the current shop session. The current user id or all segment names the current user is member of are prominent examples of such context data.

There can be multiple ContextProvider instances chained. Each ContextPro vider enriches the Context via the ContextBuilder. The resulting Context wraps a map of key value pairs. Both, keys and values have to be strings. That means if you have a more complex value, like a list, it is up to you to encode and decode it on the backend CAE side. Be aware that the parameter length can not be unlimited. Technically it is transferred via HTML headers and the size of HTML headers is limited by most HTTP servers.

CAUTION

As a rough upper limit you should not exceed 4k bytes for all parameters, as they will be transmitted via HTTP headers. You should also note that this data must be transmitted with each backend call.

All ContextProvider implementations are configured via the property com.coremedia.fragmentConnector.contextProvidersCSV in the file coremedia-connector.properties as a comma separated list. The configured ContextProvider instances are called each time a CMS fragment is requested from the *CAE* backend.

Read shop context values on the CAE side

On the backend CAE side the shop context values will be automatically provided via a Context API. You can access the context values during rendering via a Java API call.

All fragment requests are processed by the FragmentCommerceContextInt erceptor in the CAE. This interceptor calls LiveContextContextAc cessor.openAccessToContext(HttpServletRequest request) to create and store a Context object in the request. You can access the Context object via LiveContextContextHelper.fetchContext(HttpServle tRequest request).

```
import com.coremedia.livecontext.fragment.links.context.Context;
import
com.coremedia.livecontext.fragment.links.context.LiveContextContextHelper;
import javax.servlet.http.HttpServletRequest;
public class FragmentAccessExample {
    ...
    private LiveContextContextAccessor fragmentContextAccessor;
```

Commerce-led Integration Scenario | Extending the Shop Context

```
public void buildContextHttpServletRequest request() {
    fragmentContextAccessor.openAccessToContext(request);
}
public String getUserIdFromRequest(HttpServletRequest request) {
    Context context = LiveContextContextHelper.fetchContext(request);
    return (String) context.get("wc.user.id");
}
```

Example 6.3. Access the Shop Context in CAE via Context API

6.4 Solutions for the Same-Origin Policy Problem

When the commerce system has to deliver the end user's web pages, *CoreMedia Content Cloud* offers a way to enrich those web pages with content from the CoreMedia CMS; the fragment connector.

Integrating content from the CoreMedia system into the shop pages presents a challenge due to the same-origin policy:

Figure 6.6. Cross Domain Scripting with Fragments

The image above shows a typical situation when a user requests a shop page that includes CoreMedia fragments.

- 1. The page request from the end user is sent to the commerce server.
- 2. While rendering the page, the commerce server requests a fragment from the CAE.
- 3. The returned fragment contains itself parts that must be delivered dynamically. Take the login button. It is user specific, hence it must not be cached. The CoreMedia Blueprint may include such parts via Ajax requests or as ESI tags, depending on the capabilities of the component which sent the request.
- 4. The commerce server returns the complete page, including the fragment that was rendered by the CAE.
- 5. Because it is assumed that the CoreMedia eCommerce fragment contains a dynamic part, which must not be cached, the browser tries to trigger an Ajax request to the CAE. But this breaks the same-origin policy and will not succeed.

Solution 1: Access-Control-Allow-Origin

The first solution is built into the CoreMedia Blueprint workspace, so you may use it out of the box. The idea is to customize the same origin policy by setting the Access-Control-Allow-Origin HTTP header accordingly. The allowed origins can be configured via the properties cae.cors.allowed-origins-for-url-pattern[*].

```
cae.cors.allowed-origins-for-url-pattern[{path\:.*}]= \
    http://my.site.domain1,https://my.site.domain2
```

To fine-tune the configuration for Cross-Origin Resource Sharing (CORS), use the provided cae.cors configuration properties. See Section 3.1.4, "CORS Properties" in *Deployment Manual* and Section 4.3.1.8, "Solution for the Same-Origin Policy Problem" in *Content Application Developer Manual*.

Solution 2: The Proxy

To solve this problem the classical way, the Ajax request needs to be sent to the same origin than the whole page request in step 1 was. The next image shows the solution to this problem: A reverse proxy needs to be put in front of both the CAE and the commerce server.

Figure 6.7. Cross Site Scripting with fragments

Actually, you may use any proxy you feel comfortable with. The following snippet shows the configuration for a Varnish. Two back ends were defined, one for the CoreMedia eCommerce CAE named blueprint and another one for the commerce server named commerce.

The vcl_recv subroutine is called for every request that reaches the Varnish instance. Inside of it the request object req is examined that represents the current request. If its url property starts with /blueprint/, it will be sent to the CoreMedia eCommerce CAE. Any other request will be sent to the commerce system. [~ means "contains" and the argument is a regular expression]

Now, if you request a shop URL through Varnish and the resulting page contains a CoreMedia eCommerce fragment including a dynamic part that must not be cached, like the sign in button, the Ajax request will work as expected.

```
backend commerce {
    .host = "ham-its0484-v";
    .port = "80";
}
backend blueprint {
    .host = "ham-its0484";
    .port = "40081";
}
sub vcl recv {
    if (req.url ~ "^/blueprint/") {
        set req.backend = blueprint;
        } else {
            set req.backend = commerce;
        }
}
```

6.5 Caching In Commerce-Led Scenario

This section discusses the ability of using a caching proxy between the shop system and the *CAE* in the commerce-led scenario. That could be, for example, a CDN or a *Varnish Cache*. This increases the reliability of the CMS system: Fragments can be served from the cache even if the CMS is unreachable.

For this purpose, fragment requests with only static data have to be distinguished from those with dynamic personalized data. Static fragments are cacheable, but dynamic fragments are not. When the fragment delivered by the *CAE* contains personalized content, the fragment can still be cached as the DynamicInclude mechanism is used as specified in Section 6.2.1, "Using Dynamic Fragments in HTML Responses" in *Blueprint Developer Manual* for such dynamic fragments. This means the fragment with the dynamic content is fetched in a separate call with a different URL pattern. These can be handled by the proxy differently.

To enable the usage of DynamicInclude for personalized content add a Boolean property p13n-dynamic-includes-enabled to your page setting and set it to true.

You can also control how the DynamicInclude is handled. Per default if you just enable dynamic include a placement containing any personalized content (even if nested inside linked collections) will be loaded via dynamic include as a whole. In contrast to this you can add and enable the Boolean property pl3n-dynamic-includesper-item to achieve a more fine granular dynamic include. So in case the aforementioned placement contains personalized content only this content is loaded via dynamic include, making the non-personalized parts of the placement cacheable.

CAUTION

Please note that using dynamic include per item has some limitations:

It will only work as expected if the container of the personalized content [CMSelection-Rules or CMP13NSearch] is part of the rendering [more precisely: part of a render node, for example, being used as parameter self in a cm.include call]. Any mechanism that simplifies / flattens nested container structures may prevent this from happening and can cause that the personalized content might be cached.

This especially means that using the (now deprecated) getFlattenedItems method of the com.coremedia.blueprint.layout.Container interface should be avoided. Please check Section 5.16, "Rendering Container Layouts" in *Frontend Developer Manual* for a possible approach which is used in CoreMedia's example themes.

In addition to this, the dynamic include mechanism does not preserve parameters passed to the template which is being loaded via dynamic include at the moment [for example, the params parameter of the cm.include call] so you need to work around this limitation for now.

Example Request Flow

Figure 6.8. Example request flow

Figure 6.8, "Example request flow" [76] shows the commerce-led integration scenario the user requests a page with a static and a potentially dynamic CoreMedia fragment delivered by *CAE*. Note that the green arrows symbolize the flow of static content (cacheable) and the blue the flow of dynamic content. A dotted line means that the symbolized flow is optional and is omitted when the [cacheable] content is already cached.

 A user requests a shop page from the commerce server. Let's assume the shop page consists of a static and a potentially dynamic fragment. The commerce server asks the fragment connector to collect the fragments.

- 2. The connector requests CAE for the static fragment.
- The Caching Proxy intercepts the request and delivers the static fragment if already cached. Let's assume it is not or the TTL has expired, the request is forwarded to CAE.
- 4. CAE delivers the static fragment to the Caching Proxy.
- The Caching Proxy caches the static fragment and delivers it to the fragment connector.
- 6. In case of another fragment include on the commerce page the connector requests *CAE* for the potentially dynamic fragment.
- Again the Caching Proxy intercepts the request and delivers the fragment if already cached. Assuming it is not or the TTL has expired, the request is forwarded to CAE.
- 8. Assume that the CAE detects a personalized piece of content within the fragment (that cannot be cached), then it decides to deliver the fragment as DynamicIn clude. The result is still a cacheable HTML fragment but contains a link from where the dynamic fragment can be loaded. This link points to a proxy component that is part of the CoreMedia package installed in the commerce server. Such a fragment is then later retrieved via AJAX [see step 11].
- 9. The Caching Proxy caches the result even if it contains only the stub with a link to retrieve a dynamic fragment and delivers it to the fragment connector.

The HTML fragment is then post-processed by the Commerce server.

- 10. If the connector has all fragments together, the Commerce server can deliver the complete page to the requesting browser. In this case the result will contain a static CMS fragment inline and an AJAX stub with dynamic include URL that point to the Proxy Component.
- The user's browser triggers a AJAX call to the Proxy Component to load the dynamic fragment.
- 12. The Commerce server enriches the dynamic request with the user context information and the Proxy Component forwards it to the CAE. This time the dynamic request is not intercepted by the Caching Proxy. Such dynamic include URLs are always passed to the CAE. The proxy is configured accordingly.
- 13. The CAE delivers the content of the personalized dynamic fragment back to the Proxy Component.
- 14. The Proxy Component forwards the dynamic content to the user's browser after it was post-processed by the Commerce server.

The *CAE* renders the fragment adaptively. That means if no personalized content is used in a fragment, no dynamic include will be triggered. For instance, several fragments of the kind from step 2 to 5 would then be delivered.

The CoreMedia Proxy Component

The CoreMedia Proxy Component is part of *HCL Commerce Workspace* and will be installed with all other CoreMedia customizations. Technically it is a Struts Action that uses the request mapping /CmDynamic with a *url* parameter. This parameter contains an encoded *CAE* URL that is then be called by the Proxy Component, post-processed (all containing links will be generated) and the result is finally sent to the browser.

The post-processing of the received fragment payload is an important step carried out by both the Proxy Component and the *CoreMedia Fragment Connector*. At this point, their processing is similar. Links to other shop pages which may be contained in a fragment coming from the CAE must be post-processed in the Commerce system. This is because the knowledge about the final link format is in the Commerce system. In addition, other server side includes can also be done, for example, the rendering of a price info.

See the section Section 6.7.2, "How fragment links are build" [86] for more information about link building on the commerce site.

<div class="cm-fragment"
data-cm-fragment="/webapp/wcs/stores/servlet/OnDynamic?catalogId=3074457345616676719&langId=-1
&storeid=715830084&rlargid=&rl=25blugprint%?Evervlet%?Rynamic%?Placement%?Placement%?Placement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%?Flacement%

Example 6.4. AJAX Stub

The contained URL will be decoded by the Proxy Component and called on the CAE.

/blueprint/servlet/dynamic/placement/pl3n/aurora/136/placement/hero?targetView=%5Blandscape%5D &fragmentContext=/715838084/en-US/params;catalogId%3D3074457345616676719;placement%3Dhero;pageId%3Dauroraesite

Example 6.5. Effective Dynamic Include URL

Altogether there are also a few variants of these URLs which differ slightly in their path components. The identifying segment path can be filtered by the regular expression /dynamic/.+?/p13n/.A Caching Proxy in between should ignore these kinds of URLs.

Adding Context Information to Dynamic Calls

Fragments calls to the CAE can carry context information as request headers. For example that can be a membership of a customer segment or the current user id. Such information will be transmitted as HTTP request headers. Should personalized content be used, along with caching between Commerce server and *CAE* please make sure all relevant context data are provided in the *CoreMedia Fragment Connector*. Please see the Section 6.3, "Extending the Shop Context" [69]. for details.

Double Click Handler

HCL by default enables a so called DoubleClickHandler that avoids the same requests being processed in parallel. The purpose of double-click handling in WebSphere Commerce is to prevent processing the same request twice to ensure data integrity within the system. This feature prevents multiple personalized fragments on a page with dynamic Ajax loading. To use dynamic Ajax loading for multiple personalized fragments on one page set EnableDoubleClickHandler property for the Instance in *HCL Commerce* Configuration File to false or exclude the CoreMedia CmDynamic command in the DoubleClickMonitoredCommands section.

CAUTION

If the feature "Dynamic Includes in Content Fragments" stays off but personalized content is still used, the generated fragments must not be cached. Otherwise, the first user who generates such a fragment would determine the cached content.

6.6 Prefetch Fragments to Minimize CMS Requests

A shop page in the commerce-led scenario can contain multiple CMS fragments (placements and views). Normally, each CMS fragment would cause an external HTTP call to the CAE which can lead to performance loss and, depending on the commerce system, reach a limit of outgoing requests on the commerce side (see Figure 6.9, "Multiple Fragment Requests without Prefetching" [80]]. Furthermore, each request is processed consecutively. As a result, the response times for each individual CAE request add up to the total pageview time. Therefore, CAE offers a mechanism to lower the amount of CAE requests by prefetching all expected fragments in advance in a single call.

Figure 6.9. Multiple Fragment Requests without Prefetching

How to configure which fragments to prefetch

If the "prefetching feature" is enabled in the *CoreMedia Fragment Connector* on the commerce side, a dedicated *prefetchFragments* call is made to the CAE. The result is a JSON structure that consists of all fragments that are pre-rendered by the CAE. To predict the fragment calls that would normally follow, the CAE follows a twofold strategy.

• Each CMS fragment call of a single shop page should conceptually go to the "same" CMS page. Which means technically, that all the parameters that identify a CMS page should be the same in all CMS fragment calls of a single shop page (these are: *ex*-

ternalRef, productId, categoryId and pageId]. The CAE therefore uses these parameters to predict the required fragments. Every placement in the assigned page layout can be considered as "potentially to be requested". Therefore, every placement is contained as a separate fragment in the JSON result. To identify the view that should be used to render the placement a configuration is read from the *LiveContext* Settings content. The Figure 6.10, "LiveContext Settings: Prefetch Views per Placement" [82] shows an example configuration. If no setting can be found, it is assumed that the default view should be rendered for a placement.

 Additionally, every shop page requests a few more, mostly technical fragments from the CAE. These fragments are requested as different "views" of the same page. Examples of such views are metadata, externalHeadand externalFooter that are likely to be included on every shop page. These "additional views" are also read from the LiveContext Settings content and they are also included in the JSON result. The Figure 6.11, "LiveContext Settings: Prefetching Additional Views" [83] shows an example of such a configuration.

If all required fragments are already included in the prefetch result, then only one CAE fragment request is needed per shop page. All subsequent fragment calls are then served from the local fragment cache within the *CoreMedia Fragment Connector*. Thus, the configuration should be complete for each shop page type. The configuration is placed in the *LiveContext* Settings content, to be found in the Options/Set tings folder of the corresponding site and linked in the root channel. In the following sections the configuration is explained in detail.

Prefetch Configuration: View per Placement

The first configuration option is to define a view name for a certain placement. You can add this view name to the prefetch result, otherwise the default view would be rendered for this placement. Within the *livecontext-fragments* struct the *place-mentViews* sub-struct is used to store this information.

Commerce-led Integration Scenario | Prefetch Fragments to Minimize CMS Requests

 livecontext-fragments 		Struct
prefetchedViews	Struct with 3 properties	Struct
 placementViews 		Struct

view	asHeaderFragment	String
section	🗯 header	Link to 🗯 Symbol

Figure 6.10. LiveContext Settings: Prefetch Views per Placement

NOTE

The configuration needs only to be done, if there are placements that should be rendered with a different view than the default view.

Below the *placementViews* struct, two sub-elements are used:

defaults	Defines the view, a placement will be prefetched with, for all
	layouts. It overrides the default view and is itself overwritten by
	a layout specific configuration in the $layouts$ struct element.
layouts	Defines a layout-specific view with which a placement will be

prefetched. It overrides the view defined in the defaults struct element for this specific placement.

Prefetch Configuration: Additional Views

The second configuration option is the definition of additional views which should also be included into the prefetch result. Within the *livecontext-fragments* struct the *prefetchedViews* sub-struct is used for these settings.

Commerce-led Integration Scenario | Prefetch Fragments to Minimize CMS Requests

 livecontext-fragments 		Struct
 prefetchedViews 		Struct
✓ defaults		String List
#1	metadata	String
#2	externalHead	String
#3	externalFooter	String
 contentTypes 		Struct List
▼ #1		Struct
type	CMLinkable	String
 prefetchedViews 		String List

#2	asBreadcrumb	String
#3	externalHead	String
#4	externalFooter	String
placementViews	Struct with 1 property	Struct

Figure 6.11. LiveContext Settings: Prefetching Additional Views

Below the *prefetchedViews* struct three sub-elements are used:

defaults	Defines the views that should be additionally prefetched for all layouts. It is overwritten by a layout specific config- uration in the layouts element.
layouts	Defines the views that should be additionally prefetched for a specific layout. It overwrites the configuration in the defaults struct element.
contentTypes	Defines the views that should be prefetched for a specific content type on Content Pages [see Section 6.2, "Adding CMS Fragments to Shop Pages" [56] for a definition of Content Page] [for example, a page that has a CMS article as main content].
	Content Pages can contain CMS content of different types. For each type you can configure a struct with views that will be prefetched. You can use abstract or parent content

types to combine multiple types [CMLinkable, for instance].

If more than one configured content type can be applied to a given content, the configuration for the most specific content type will prevail. For example when CMLink able and CMChannel are configured, then for a CMChannel content item only the configuration for CMChannel will be taken into account.

To define the default view to be additionally prefetched, use the DEFAULT identifier.

Configuration in HCL Commerce

The prefetch functionality is enabled by default. It can be enabled or disabled via property com.coremedia.fragmentConnector.isPrefetchEnabled in coremedia-connector.properties.

6.7 Link Building for Fragments

If you include CoreMedia fragments into *HCL Commerce* pages, these fragments might contain links to commerce pages; a link to an Augmented Category, for example. Depending on the scenario that you use, this link should led to a page rendered by the CAE (content-led scenario) or to a page rendered by the *HCL Commerce* (commerce-led scenario). The latter is named "deep link".

6.7.1 Configuring Deep Links

A use case for deep links might be the following: You have an existing eCommerce solution with carefully styled category and product pages. While you want to switch to *Content Cloud* in order to enhance your site with editorial content, there is no need to port the commerce pages to *Content Cloud*. Instead, you want to reuse the existing pages (possibly enhanced with *Content Cloud* fragments).

Content Cloud supports two settings to switch to deep links for categories and products:

- livecontext.policy.commerce-product-links
- livecontext.policy.commerce-category-links

The settings are at the root channel of each site. The default setting is true, which means that the CAE creates deep links to the product or category pages of the *HCL Commerce*. However, for links to other content types, such as HTML, CSS or JavaScript, links to the CAE will be generated. Also, URLs to dynamic resources (UriConstants.Prefixes.PREFIX_DYNAMIC) won't be converted to JSON. See Section 8.3, "Enabling Preview in Shop Context" [103] to learn how to enable the preview for *HCL Commerce* pages in *Studio*.

The settings are evaluated by the LiveContextPageHandlerBase and its subclasses.

If a setting is true, the corresponding @Link method creates links to *HCL Commerce*, so there is no need for a matching @RequestMapping method. If it is false, the @Link method creates CAE links. So you must keep the according @RequestMapping method in sync with changes to the URL pattern and provide [or customize] the ProductPageHandler or ExternalNavigationHandler classes. See also the Section 4.3, "The CAE Web Application" in *Content Application Developer Manual* for request handling and link building.

Overview

Properties for deep link activation

Default setting "true"

Link building and request handling

6.7.2 How fragment links are build

Each lc:include tag requests an HTML fragment via HTTP from the CAE. Every link within a fragment that is requested by the commerce system from the CAE is processed by the LiveContextLinkTransformer class. The transformer only applies for fragment requests and finally requests URL templates from the LinkRepository on the Commerce Adapter side. For fragment request the Commerce Adapter returns JSON strings to the CAE. Each of these JSON objects contains at least the values of the constants objectType and renderType and the ID of the content or commerce object.

Assume the HTML fragment contains a link to a CMArticle content item. Instead of rendering the regular link, for example

http://cae-host/blueprint/servlet/page/mySite/mySegment/mySeoContent-4712

the corresponding Link generated by the LiveContextLinkResolver would look like:

```
a href="<!--CM {
    "id":"cm-1696-4712",
    "renderType":"url",
    "externalSeoSegment":"mySeoContent-4712",
    "objectType":"content"}
    CM-->"...
```

The CoreMedia Fragment Connector on the commerce side parses the JSON, identifies the object type and rendering type and applies a template to render a commerce link. For the given example, the template Content.url.jsp is used, applied by the pattern "<OBJECT_TYPE>.<RENDER_TYPE>.jsp".

The JSP file on the commerce side finally generates the resulting URL.

```
http://localhost/webapp/wcs/stores/servlet/CoreMediaContentURL?
storeId=10202&externalSeoSegment=spring-salads-1888&
urlRequestType=Base&langId=-1&catalogId=10051
```

Example 6.6. Commerce URL

NOTE

The SEO feature has not been configured for this example, otherwise the extern alseoSegment value would be used to render a SEO friendly URL.

Other templates are located in the folder workspace\Stores\WebCon tent\Widgets-CoreMedia\com.coremedia.commerce.store.wid

gets.CoreMediaContentWidget\impl\templates by default. The path is configurable via property com.coremedia.widget.templates in core media-connector.properties. New templates can be added by extending the CommerceLinkResolver in the *Blueprint* workspace. Custom object types can be added, depending on the content type of the content or its property values. Also, additional rendering types can be defined for an object type. Using this templating mechanism, it is possible to support different layouts for content depending on its context.

7. Content-led Integration

In the content-led scenario, *HCL Commerce* system and CMS system are equal partners. It is possible, that the CoreMedia CAE delivers all content to the customer, while augmenting the pages with content, such as prices, from the commerce system.

- Section 7.1, "Content-led Integration Overview" [89] gives an overview over the request flow in the content-led scenario.
- Section 7.2, "Status Synchronization in the Content-led Integration Scenario" [91] describes how the user state is synchronized between the commerce system and CMS systems.

NOTE

This chapter does not apply to *HCL Commerce* 9.1. More information on the Headless Integration Scenario can be found in Chapter 4, *Supporting HCL Commerce* 9.1 [38].

Ī.

7.1 Content-led Integration Overview

Figure 7.1. Content-led integration scenario

The most obvious difference to the commerce-led scenario in the content-led scenario is the presence of a second virtual host, that separates both systems, the *CAE* and the commerce system, clearly from one another. Here the *CAE* is the fully equal partner of the commerce system with the potential to become the driving force for rendering the whole front end.

The description of a typical request flow through the system, as shown in Figure 7.1, "Content-led integration scenario" [89], clarifies the different roles of the *CAE* and the commerce system in this scenario.

- 1. The user requests a marketing driven landing page of a shop system.
- 2. The virtual host for the CAE forwards the request to the CAE.
- 3. Part of the requested page are various product teasers, with dynamic prices. Hence, the *CAE* needs to fetch corresponding information from the commerce system.
- 4. After receiving the page from the CAE, the user decides to click on a product teaser to see the corresponding product details. The link, rendered by the CAE as part of the landing page, directs the user to the virtual host of the commerce system.
- 5. The virtual host forwards the request to the commerce server.

As the requested Product Detail Page (PDP) contains a CoreMedia fragment, the commerce system requests it from the CAE and sends the whole PDP back to the user.

From the example follows, that the commerce-led integration scenario described in Chapter 6, *Commerce-led Integration Scenario* [53] is a subset of the content-led scenario. The request flow 4->-5->-6 uses the exact same technique to handle included CoreMedia fragments into *HCL Commerce* pages as described in the commerce-led scenario. The only difference is that resources or dynamic fragments fetched via Ajax requests are not handled by the virtual host of the commerce system. Instead, they are sent to the CAEs virtual host.

7.2 Status Synchronization in the Content-led Integration Scenario

Motivation

Take a look at figure Figure 7.1, "Content-led integration scenario" [89]. As you can see, the CAE and the commerce system stand side by side as equal partners from a users point of view. A user is allowed to request pages from both systems at any given time.

This architecture forces the CAE to synchronize any user sessions on the commerce system with its own. A user that browses the CAE and afterwards visits the *HCL Commerce* must keep his session and vice versa a user browsing the *HCL Commerce* going to the CAE afterwards must keep his state as well.

This section describes how the synchronization of this state is implemented by the CoreMedia CAE.

7.2.1 What Is The Users State?

HCL Commerce represents the state of a user session using cookies. To understand the synchronization of a users state across both systems you need to understand how those cookies may flow through the system. Take a closer look at Figure 7.2, "Content-led integration scenario with cookies" [92]. In addition to the request flow, the dashed green and blue arrows represent the flow of cookies.

Content-led Integration | What Is The Users State?

Figure 7.2. Content-led integration scenario with cookies

You can see that cookies may flow nearly everywhere. No matter where a request starts and where it ends, either between the browser and the *CAE* or between the *CAE* and the *HCL Commerce* system, every node may be the source as well as the receiver of cookies.

Two things that need explanation. First, two kinds of cookies flow from the browser to the *CAE*, cookies which were originally created in the commerce system and cookies that are created by the *CAE*. This is necessary because the *CAE* must send the commerce cookies to the commerce system as part of its backend calls. Second, for fragment requests [labeled with 6], no CoreMedia cookies are needed, hence, the browser does not need to send the *CAE* cookies to the commerce server.

Therefore, CoreMedia had to answer the following questions:

7.2.1.1 How does the CAE render fragments without its own cookies?

Cookies are used for dynamic HTML snippets, which are snippets that cannot be cached because they contain user specific content. Fragments that the *CAE* delivers to the commerce server should never include such dynamic HTML snippets because this would prevent a CDN or other caching infrastructure from caching complete *HCL Commerce* pages.

7.2.1.2 How Does the Browser Deliver Commerce System Cookies to the CAE?

The browser sends cookies to a server that runs in the same domain, that is saved with the cookie. In general the cookie domain of a cookie is left empty, so that the browser stores the exact host name of the server that responded to a request. But because the *CAE* and the commerce system must have different host names (via their virtual host), the *CAE* would never receive commerce system cookies.

Figure 7.3. Content-led integration scenario

The solution to this problem is fairly simple. A servlet filter, the so called cookie leveler, runs in front of any *HCL Commerce* storefront call. It wraps the HttpServletRe sponse into a custom one, that intercepts addCookie() method calls in order to set the cookie domain to a configurable value.

The cookie leveler should be executed prior to any other filter that may add cookies to the response. In general CoreMedia recommends you to put its filter mapping definition in front of any other filter mapping.

There is one cookie that cannot be customized that way, the JSESSION cookie, which is set by the WebSphere servlet container. You have to configure it via the usual mechanisms provided by HCL, for example via the HCL console.

Now the CAE and the commerce system only need to be put into the same domain, for example helios.docker.localhost for the CAE and shop-helios.docker.localhost for the *HCL Commerce* system. The cookie domain must then be configured to be .docker.localhost

NOTE

The cookie domain must not be a top level domain, for example .com, because that would mean, every website in the .com domain will receive the cookies. Because that does not make any sense, cookies with only a top level domain are generally not sent at all.

i.

8. Studio Integration of Commerce Content

CoreMedia Content Cloud integrates with HCL Commerce Server. In the following it is simply called the "commerce system" or "the shop".

From classical shop pages, like a product catalog ordered by categories or product detail pages up to landing pages or homepages, all grades of mixing content with catalog items are conceivable. The approach followed in this chapter, assumes that items from the catalog will be linked or embedded without having stored these items in the CMS system. Catalog items will be linked typically and not imported.

- Section 8.1, "Catalog View in CoreMedia Studio Library" [96] gives a short overview over the Catalog Integration in the *Studio* Library.
- Section 8.2, "HCL Management Center Integration in CoreMedia Studio" [101] gives a short overview over the HCL Commerce Management Center integration in CoreMedia Studio.
- Section 8.4, "Commerce related Preview Support Features" [104] gives a short overview over the commerce related preview functions that are supported in *CoreMedia Studio*.
- Section 8.5, "Augmenting Commerce Content" [108] describes how you augment commerce content in the commerce-led scenario in *CoreMedia Studio*.

8.1 Catalog View in CoreMedia Studio Library

When the connection to a *HCL Commerce* system and a concrete shop for a content site are configured as described in Section 5.1, "Configuring the Commerce Adapter" [41] the *Studio* Library shows the default commerce catalog. You can also configure multiple catalogs as described in section "Configuring Multiple Catalogs" [45]. Then you will see all configured catalogs in the library. You can browse product categories, products and marketing spots in the commerce catalog and search for products, product variants and marketing spots. After the editor has selected a preferred site with a valid store configuration the catalog view will be enabled and the catalog[s] will be shown in the Library:

Figure 8.1. Library with catalog in the tree view

In some catalogs it is possible to put a category on multiple places within the catalog tree. But the Commerce Hub ensures that a category can only have one home (a unique parent category). All additional occurrences of a category are shown as a link in the tree. If you click on such a link node you will automatically end up at the place in the tree where the category is actually at home.

Figure 8.2. Library tree with multiple occurrences of the same category

These catalog items can be accessed and assigned to various places within your content. For example, an *eCommerce Product Teaser* content item can link to a product or product variant from the catalog. The product link field (in *eCommerce Product Teaser* content item) can be filled by drag and drop from the library in catalog mode.

Linking a content (like the *eCommerce Product Teaser*) to a catalog item leads to a link that is stored in the CMS content item and references the external element. Apart from the external reference (in the case of the commerce system it is typically a persistent identifier like the product code for products) no further data will be imported (importless integration).

While browsing through the catalog tree you can also open a preview of a category or a product from the library. Simply double-click on a product in the product list or use the context menu on a product or a category and choose the entry **Open in Tab** from the context menu as shown in the pictures below.

Figure 8.7. Category in tab preview

Figure 8.8. Category in tab preview [HCL Commerce 9.1]

In addition to the ability to browse through the commerce catalog in an explorer-like view it is also possible to search for products, variants and marketing spots from catalog. Similar to the content search, if you are in the catalog mode and you type a search keyword into the search field and press **Enter**, the search in the commerce system will be triggered and a search result will be displayed.

8.2 HCL Management Center Integration in CoreMedia Studio

NOTE

The HCL Management Center Integration is only available if the HCL Commerce Extension is used.

In addition to the eCommerce catalog library integration you can directly access the *HCL Management Center* from *CoreMedia Studio*. A context menu action on a product, product variant, category or e-marketing spot opens the item in a window within *Core-Media Studio* where catalog item properties can be edited directly. This applies to all components in *CoreMedia Studio* which represent a product, product variant, category or e-marketing spot. Categories in the library do not open in Management Center by double click as this is the default behavior for navigation in the library tree.

Figure 8.9. Management Center in Studio
NOTE

Known restriction:

- Up to FEP 7, the only supported web browsers are Internet Explorer and Firefox as these are supported web browsers for *HCL Commerce Server* Tools. Since FEP 8, Chrome is also supported.
- Currently there is no Single Sign On implemented between *CoreMedia Studio* and *Management Center*. You have to login to the *Management Center* with your *HCL Commerce* login credentials.

i.

8.3 Enabling Preview in Shop Context

CoreMedia Content Cloud enables you to directly preview pages for not augmented or augmented products, not augmented or augmented categories and CoreMedia channels in *CoreMedia Studio* within the shop context (as a shop page with the shop frame around it). Otherwise, you would get a CoreMedia-typical fragment preview that shows a content item with multiple views.

To enable the preview of Category Pages in the shop context, add a Boolean property livecontext.policy.commerce-category-links to your LiveContext settings and set the value "true".

To enable the preview of Product Pages in the shop context, add a Boolean property livecontext.policy.commerce-product-links to your LiveContext settings and set the value "true".

To enable the preview of CoreMedia Channels in the shop context, add a Boolean property livecontext.policy.commerce-page-links to your LiveContext settings and set the value "true".

In order to enable the preview of Commerce category pages in Studio, proceed as follows:

- Open the CommonJSToInclude.jspf file and ensure that \${jsAssets Dir}javascript/CoreMedia/coremedia-pbe.js is included if cm page pbe pageData is not empty.
- 2. In the studio-server app, the studio.previewUrlWhitelist property must contain the commerce URL [including the port, for example *core media.com or http://localhost:40080]. Be aware that this property overwrites the studio.previewUrlPrefix property, so you have to add the default CAE preview URL to the studio.previewUrlWhitelist property too.

NOTE

If your *HCL Commerce* shop storefront uses any clickjacking prevention features (for example, X-Frame-Options [see https://help.hcltechsw.com/commerce/8.0.0/ad-min/tasks/tseiframerestrictxframe.html for details), please make sure to allow the shop preview (*HCL Commerce* Staging-/Authoringserver) being embedded as an iframe within *CoreMedia Studio*.

8.4 Commerce related Preview Support Features

CoreMedia Studio supports a variety of commerce preview functions directly:

• Time based preview (time travel)

When a preview date is set in *CoreMedia Studio*, it sets the virtual render time to a time in the future. If the currently previewed page contains content from the commerce system, it is desirable that also these content reflects the given preview time. That could be a marketing spot containing activities with different validity time ranges. A specific activity could be valid only after a certain time or a marketing teaser that announces a happy hour could be another example.

If such preview is requested from *HCL Commerce* the preview date is also sent to *HCL Commerce* as a genuine *HCL Commerce* preview token. The *HCL Commerce* recognizes the transmitted preview date and renders a control on top of the page that lets you inspect the currently active settings. Figure 8.10, "Time based preview affects also the *HCL Commerce* preview" [105] gives an example.

Figure 8.10. Time based preview affects also the HCL Commerce preview

• Customer segment based preview

The commerce segment personalization is not available in HCL Commerce (FEP6).

FEP7+

The feature segment based preview supports the creation of personalized content. In this case, content is shown depending on the membership in specific customer segments. In addition to the existing rules, you can define rules that are based on the belonging to customer segments that are maintained by the commerce system.

These commerce segments will be automatically integrated and appear in the chooser if you create a new rule in a personalized content. For a preview, editors can use test personas which are associated with specific customer segments.

Figure 8.11, "Test Customer Persona with Commerce Customer Segments" [106] shows an example where the test persona is female and has already been registered.

Studio Integration of Commerce Content | Commerce related Preview Support Features

Figure 8.11. Test Customer Persona with Commerce Customer Segments

Such preview settings apply as long as they are not reset by the editor.

The test persona content can be created and edited in *CoreMedia Studio*. The customer segments available for selection will be automatically read from the commerce system. By default, all user segments available in the eCommerce system are displayed for selection. Under some circumstances it may be desirable to restrict the shown user segments, for instance for studio performance reasons or for better clarity for the editor. See Section 3.2.4, "Configuring The PersonaSelector" in *Personalization Hub Manual*.

Figure 8.12. Edit Commerce Segments in Test Customer Persona

For personalized content based on commerce customer segmentation, it depends on the content type, if rules can be applied in the different rendering scenarios. In the case of catalog items, like products and categories, the commerce-led and the content-led scenarios are supported. In the content-led scenario the *CoreMedia CAE* is responsible for rendering, but the given user ID is also sent to the *HCL Commerce*. So all content that is received from the *HCL Commerce* is delivered within the context of the current *HCL Commerce* user. For marketing spots, the commerce system is responsible for rendering and therefore only the commerce-led scenario is supported.

The commerce segments that the current user belongs to are available during the rendering process within a *CoreMedia CAE*. Thus, content from the CoreMedia system can also be filtered based on the current commerce segments.

In the other direction, if the personalized content is integrated within a content fragment on a shop page, the current commerce user is also transmitted as a parameter. Thus, the CoreMedia system can retrieve the connected customer segments from the commerce system in order to perform commerce segment personalization within the supplied content fragments.

8.5 Augmenting Commerce Content

In the commerce-led scenario you can augment pages from the Commerce System, such as products (Product Detail Pages), categories (Category Overview/Landing Pages) and other shop pages (like the Contact-Us Page linked from the Homepage Footer). The following sections describe the steps required in *Studio*.

Extending a shop page with CMS content comprises the following steps, which will be explained in the corresponding sections.

- In the CMS create a content item of type Augmented Category, Augmented Product or Augmented Page.
- Augment the root nodes of the catalogs as described in Section 8.5.1, "Augmenting the Root Nodes" [108].
- 3. When you augment a category or product, the connection between the category/product and the Augmented Category/Augmented Product content is automatically created. For the Augmented Page you have to create this connection manually via an external page id property
- 4. In the Augmented Category, Augmented Product or Augmented Page choose a page layout that corresponds to the shop page layout. It should contain all the placements that are referenced in the *CoreMedia Content Widgets* defined on the Commerce side.
- Drop the augmenting content into the right placements of the augmented content item. That is, into a placement whose name corresponds with the name defined in the CoreMedia Content Widget.

8.5.1 Augmenting the Root Nodes

If the shop connection is properly configured, you will see an additional top level entry in the *Studio* library that is named after your store (for example, *AuroraESite*,). Below this node you can open the *Product Catalog* with categories and products. The *Product Catalog* node also represents the root category of a catalog.

When multiple catalogs are configured, you will see multiple nodes under the store node. They represent catalogs' root categories. Each catalog has the *HCL Commerce* code of the catalog as its name.

To have a common ancestor for all augmented catalog pages, every root node of all configured catalogs must be augmented. You can augment the root category by clicking *Augment Category* in the context menu of the root category. An augmented category content opens up, where you can start to define the default elements of your catalog

Catalog view in Studio

Augmented catalog roots

pages, like the page layouts for the Category Overview Pages (CLP) and Product Detail Pages (PDP) and first content elements. All sub categories, augmented or not, will inherit these settings. See Section 6.2.3, "Adding CMS Content to Your Shop" in *Studio User Manual* for more information.

Figure 8.13. Catalog structure in the catalog root content item

Now, you can start augmenting sub categories of the catalog. All content and settings are inherited down in this hierarchy.

8.5.2 Selecting a Layout for an Augmented Page

CoreMedia Content Cloud comes with a predefined set of page layouts. Typically, this selection will be adapted to your needs in a project. By selecting a layout an editor specifies which placements the new page will have, which of them can be edited and how the placements are arranged generally. It should correspond to the actual shop page layout. All usable placements should be addressed. The placement names must match the placement names used in the slot definition on the shop side.

Figure 8.14. Choosing a page layout for a shop page

If you augment a category, the corresponding Augmented Category content item contains two page layouts: the one in the *Content* tab is applied to the Category Overview Page and the other in the *Product Content* tab is used for all Product Detail Pages. Both layouts are taken from the root category. The layouts that are set there form the default layouts for a site. Hence, they should be the most commonly used layouts. If you want something different, you can choose another layout from the list.

8.5.3 Finding CMS Content for Category Overview Pages

A category overview page is a kind of landing page for a product category. If a user clicks on a category without specifying a certain product, then a page will be rendered that introduces a whole product category with its subcategories. Category overview pages contain a mix of product lists with and promotional content like product teasers, marCategory overview pages

keting content [that can also be product teasers but of better quality] or other editorial content.

You can use the *CoreMedia Content Widget* in the commerce-led scenario in order to add content from the CoreMedia CMS to the category overview page.

Figure 8.15. Category Overview Page with CMS Content

When a category page contains the *CoreMedia Content Widget*, then on request, the current category ID and the name of the placement configured in the *CoreMedia Content Widget* are passed to the CoreMedia system. The CoreMedia system uses this information to locate the content in the CoreMedia repository that should be shown on the category overview page.

Content Cloud tries to find the required content with a hierarchical lookup using the category ID and placement name information. The lookup involves the following steps:

Content Cloud tries to find the required content with a hierarchical lookup, performing the following steps:

- 1. Select the Augmented Page that is connected with the shop.
- 2. Search in the catalog hierarchy for an Augmented Category content item that references the catalog category page that should be augmented and that contains a placement with the name defined in the *CoreMedia Content Widget*.

Information passed to the CoreMedia system

Locating the content in the CoreMedia system

- a. If there is no *Augmented Category* for the category, search the category hierarchy upwards until you find an *Augmented Category* that references one of the parent categories.
- b. If there is no Augmented Category at all, take the site root Augmented Page.
- 3. From the Augmented Category content found take the content from the placement which matches the placement name defined in the *CoreMedia Content Widget*.

Figure 8.16, "Decision diagram" [112] shows the complete decision tree for the determination of the content for the category overview page or the product detail page [see below for the product detail page].

Figure 8.16. Decision diagram

Keep the following rules in mind when you define content for category overview pages:

- You do not have to create an Augmented Category for each category. It's enough to create such a page for a parent category. It is also quite common to create pages only for the top level categories especially when all pages have the same structure.
- You can even use the site root's Augmented Page to define a placement that is inherited by all categories of the site.
- If you want to use a completely different layout on a distinct page (a landing page's layout, for example, differs typically from other page's layouts), you should use different placement names for the "Landing Page Layout", for example with a landing-

page prefix (as part of the technical identifier in the struct of the layout content item). This way, pages below the intermediate landing page, which use the default layout again, can still inherit the elements from pages above the intermediate page (from the root category, for instance), because the elements are not concealed by the intermediate page.

8.5.4 Finding CMS Content for Product Detail Pages

Product detail pages give you detailed information concerning a specific product. That includes price, technical details and many more. You can enhance these pages with content from the CoreMedia system by adding the *CoreMedia Content Widget* similar to the category overview page.

Product Detail Pages

Figure 8.17. Product detail page with CMS content in the Banner section and empty Header placement

Similar to the category overview pages, the Category ID and placement name are passed to *Content Cloud* in order to locate the content.

For product detail pages, the page can be directly augmented with an Augmented Product content type. If this is not the case, *Content Cloud* uses the same lookup as described for the category overview page. The only slight difference that the site root Augmented Page content item is not considered as a default for the product detail page.

Information passed to the CoreMedia system

Locating the content in the CoreMedia system The content to augment is taken from a separate page grid of the Augmented Category, called *Product Content* or from the *Content* tab of the Augmented Product.

Adding CMS Assets to Product Detail Pages

You can enhance product detail pages with assets from the CoreMedia system by adding Protected the CoreMedia Product Asset Widget.

Product detail pages

Figure 8.19. Product detail page with CMS assets

The Product ID and orientation are passed to *Content Cloud* in order to locate and layout the assets.

To find assets for product detail pages, *Content Cloud* searches for the picture content items which are assigned to the given product. These items are then sorted in alphabet-ical order. See Section 6.6, "Advanced Asset Management" in *Blueprint Developer Manual* for details.

Information passed to the CoreMedia system.

Locating the assets in the CoreMedia system

8.5.5 Adding CMS Content to Non-Catalog Pages (Other Pages)

Non-catalog pages (Augmented Pages) like 'Contact Us', 'Log On' or even the homepage are shop pages, which can also be extended with CMS content. The homepage case is quite obvious. The need to enrich the homepage with a custom layout and a mix of promotional and editorial content is very clear. However, the less prominent pages can also profit from extending with CMS content. For example, context-sensitive hotline teasers, banners or personalized promotions could be displayed on those pages. Non Catalog Pages [Other Pages] You can augment a non-catalog page with *Studio* using the preview's context menu. In the *Studio* preview, navigate to the non-catalog page that should be augmented, right-click its page title and select *Augment page* from the context menu.

You can also perform the following steps using the common content creation dialog:

- Make sure, that the layout of the page in the commerce system contains the Core-Media Content Widget.
- 2. Create a content item of type *Augmented Page* and add it to the *Navigation Children* property of the site root content.
- 3. Enter the ID of the other page below the navigation tab into the *External Page ID* field of the Augmented Page.
- 4. Optional: Set the External URI Path if special URL building is needed.

In the following example a banner picture was added to an existing "Contact Us" shop page. To do so, you have to create an *Augmented Page*, select a corresponding page layout and put a picture to the *Header* placement.

Figure 8.20. Example: Contact Us Pagegrid

The case to augment a non-catalog page with *CoreMedia Studio* differs only slightly from augmenting a catalog page. You use Augmented Page instead of Augmented Category and instead of linking to a category content, you have to enter a page ID in the *External Page ID* field. The page ID identifies the page unambiguously. Typically, it is the last part of the shop URL path without any parameters.

Difference between the augmentation of catalog and other pages

```
https://<shop-host>/<some-path>/contact-us
```

The URL above would have the page id contact-us that will be inserted into the *External Page ID* on the *Navigation* tab. In case of a standard "SEO" URL without the need of any parameters the *External URI Path* field can be left empty.

* Navigation		
X 🖊 🐰 🔒 🔓		
➡ Add content by draggin	g it from the Library here.	
Visibility		
 Enhanced Page 		
External Page ID		
External Page ID AdvancedSearchDisplay		
External Page ID AdvancedSearchDisplay External URI Path		

Figure 8.21. Example: Navigation Settings for a simple SEO Page

When the URL to a shop page is not a standard SEO URL but contains, for example, additional parameters, you can add this additional information via the *External URI Path* field (see Figure 8.22, "Example: Navigation Settings for a custom non SEO Form" [118]]. This is necessary in order to get the *Studio* preview for the augmented page or for links rendered from the CMS. Therefore, if you have entered the correct URL, you will see the page in the preview.

In the *External URI Path* field, you redefine the URL path starting from /en/au rora/... and add required parameters. For example the advanced search page does not use the standard SEO path and in turn it has additional parameters:

.../AdvancedSearchDisplay?catalogId=10152&langId=-1&storeId=10301

Some of the standard parameters are well known and can be replaced by tokens, because they are very typical for all such URLs. In order to flexibly copy these URLs to other sites with different shop configurations the following tokens can be used:

Token	Description
storeId	The current store ID.
catalogId	The current catalog ID.

URLs of non SEO pages

Studio Integration of Commerce Content | Adding CMS Content to Non-Catalog Pages (Other Pages)

Token	Description
langId	The current language ID.

Table 8.1. config.id

Tokens have to be enclosed with curly braces. In case of the Advanced Search Page it would be possible to enter to following String into the *External URI Path*:

/AdvancedSearchDisplay?catalogId={catalogId}&langId={langId}&storeId={storeId}

AdvancedSearchDisplay					
External URI Path					

Figure 8.22. Example: Navigation Settings for a custom non SEO Form

NOTE

Be aware that the property *External Page ID* must be unique within all other "Other Pages" of that site. Otherwise, the rendering logic is not able to resolve the matching page correctly. A validator in *CoreMedia Studio* displays an error message, if a collision of duplicate *External Page ID* values occurs. Your navigation hierarchy can differ from the "real" shop hierarchy. There is also no need to gather all pages below the root page. You can completely use your custom hierarchy with additional pages in between, that are set *Hidden in Navigation* but can be used to define default content for are group pages.

Special Case: Homepage

The home page of the site is the main entry point, when you want to augment a commerce catalog. In the commerce-led scenario, it is a content item of type Augmented Page. While in a content-led scenario, it would be of type Page. Special Case: Homepage The *External Page ID* field can be left empty. The homepage is anyway the last instance that will be chosen if no other page can be found to serve a fragment request.

The *External URI Path* field is also likely to remain empty, unless the shop site is to be accessible with an URL, which still has a path component [for example, .../en/au rora/home.html]. But in most cases you wouldn't want that.

Figure 8.23. Special Case: Navigation Settings for the Homepage

9. Commerce Caching

The CoreMedia system uses caching to speed-up access to various eCommerce entities (e.g. catalogs, categories, products, segments etc.). These entities are cached when they are requested by the CoreMedia system.

Commerce-Hub Cache Infrastructure

Caching of commerce entities is implemented in different layers of the Commerce Hub infrastructure:

Figure 9.1. Multiple levels of caching

- Caching is implemented in the Commerce Adapter to accelerate access to commerce entities and to avoid heavy traffic on the HCL Commerce system due to multiple clients connected to the same system.
- Caching is implemented in the Commerce Adapter client library which is used in Studio, Content Application Engine, *Headless Server* and Content Feeder. This avoids redundant network communication with the Commerce Adapter when accessing commerce entities.
- Caching is implemented in the Studio Client. Commerce entities are loaded as RemoteBeans and take part in the *Studio* invalidation mechanism. Updates can be displayed directly if they are recognized.

Java based apps like the Commerce Adapter and Commerce Adapter clients, e.g., Studio, Content Application Engine, *Headless Server*, and Content Feeder, use the CoreMedia Cache to cache commerce entities.

NOTE

It is recommended to cache as many commerce entities as possible in the Commerce Adapter for a rather long time and to enable both immediate recomputation and persistent caching of messages as described further down in this chapter. Commerce client apps may then be configured to use rather small caching times and small capacities for commerce entities.

Cache Invalidation by Actuator

Commerce entities are cached for a configurable time span. Changes made to commerce items on the *HCL Commerce* won't be visible until this cache time expires. Two issues arise when only relying on the expiry of cache keys.

First, a proper adjustment of the cache times compromises between two requirements: On the one hand cache times should be short in order to provide an up-to-date system. On the other hand cache times should be long in order to reduce the traffic on the *HCL Commerce*. Second, updating a cache entry requires a controlled invalidation across all relevant caches of the Commerce Hub infrastructure. It is not sufficient to have a cache entry expire in one cache if other caches are still returning the old value.

The Commerce Adapter is the central component that addresses both issues. It allows for a proactive invalidation of cache entries via the invalidate actuator and it informs all connected caches about this invalidation. Each client connects as an invalidation observer to the adapter and is notified when a cache entry is to be invalidated. The propagation of the invalidation event ensures that all connected client caches are also updated.

The actuator can be triggered manually or via custom scripts depending on the workflow of the connected *HCL Commerce*. If the update cycles of the *HCL Commerce* are known or if changes can be detected automatically and be used to trigger a script invoking the invalidate actuator, then long cache times can be configured to hold commerce entities in the cache as long as possible.

The following figure shows the actuator component in the Commerce Adapter and the direction of events propagating the invalidation.

The actuator can be called by using a POST request.

http://<adapter-host>:<adapter-port>/actuator/invalidate

The body is of JSON code with 2 mandatory parameters; all must be present but can also be left empty.

type The entity type. Can be one of the following values: catalog, cat egory, product, segment, marketing_spot. Further values can be registered in a project customization. If it is empty, the value remains unspecified and, for example, all items with the given *type* are invalidated.

id The entity ID. If it is empty, all items of an entity type are invalidated.

Examples:

```
{
  "type": "product",
  "id": "dress-3"
}
```

Invalidate product dress-3 in the Commerce Adapter and in all connected clients.

Invalidate category *dresses* in the Commerce Adapter and in all connected clients.

```
"type": "category",
```

Commerce Caching |

```
"id": "dresses"
}
{
    "type": "category",
    "id": ""
}
```

"type": "", "id": "" Invalidate all categories in the Commerce Adapter and in all connected clients.

Invalidate all commerce items in the Commerce Adapter and in all connected clients (invalidate all).

NOTE

If a client misses a notification, for example because it is unavailable, it would continue to deliver the old value until the next invalidation comes in, either via actuator or timeout. If there is any suspicion that a cache is out-of-sync, the actuator can be called again.

Invalidation messages from Commerce Adapter to the connected clients can also be turned off using the following configuration property. Then the cache items in the clients disappear only after they have expired. Invalidation messages are turned on by default.

```
entities.send-invalidations=true
```

NOTE

Please note, there is no automatic mechanism involved that is able to trigger the invalidation when a commerce item is changed in the *HCL Commerce*. Such a mechanism can be provided in projects.

Immediate Recomputation of Cache Keys

Commerce entities can be recomputed immediately if they are invalidated in the Commerce Adapter using the following configuration property. This feature is useful to keep the cache of the Commerce Adapter filled with the most frequently used commerce entities. The feature is turned off by default. entities.recompute-on-invalidation=true

NOTE

Recomputation is triggered no matter if the invalidation was send from the cache timer or the invalidate actuator. Cache keys that are evicted due to space considerations of the cache are not recomputed.

Persisted Caching of gRPC Messages

Incoming and outgoing gRPC messages can be saved to disk to speed-up the Commerce Adapter. This feature allows the Commerce Adapter to read messages from disk when started and to use the restored messages for the following two purposes:

- Immedately respond to requests with the restored response.
- Replay the restored requests so that the cache fills with up-to-date values served by the *HCL Commerce*.

When all requests have been replayed the restored messages are discarded so that responses are only taken from the commerce cache. New incoming requests and their responses are saved to disk using the allowed maximum number of files configured via entities.message-store.files.The allowed number of files default to the configured cache capacities as described in the next section. The feature is turned off by default but can be enabled by setting the following configuration property so that it points to an existing directory.

entities.message-store.root=file://<PATH TO DIRECTORY>

WARNING

The directory configured via entities.message-store.root must not be a shared directory.

NOTE

The contents of the directory configured via entities.message-store.root may be copied so that new Commerce Adapter instances read messages written by another Commerce Adapter.

Cache Configuration of the Commerce Adapter

NOTE

This chapter applies to the Commerce Adapter, but not to the generic clients like Studio, Content Application Engine, *Headless Server* and Content Feeder.

i

In order to adjust the cache configuration you can use the following properties for cache capacities and cache timeouts respectively:

- cache.capacities.*
- cache.timeout-seconds.*

The last part of the configuration property is the config key. Each cache key, e.g. for a product, is using its well known config key (e.g. product) to set the capacity and the cache time. The cache capacity denotes the number of commerce entities that the cache can hold of a specific cache class while the cache time specifies the duration that the cache can hold a commerce entity.

There are 2 types of config keys, those that are the same for all different commerce adapters and those that are specific to each vendor adapter. A wide part of the caching is already done within the base adapter library on Service level [e.g. the ProductService] and does not have to be done in each vendor specific adapter.

Common base adapter config keys:

catalogs	The list of all catalogs for a store referenced by ID and the definition of the default catalog.
catalog	A catalog with its properties and a reference to the root category.
category	A category with its properties. Sub-categories are referenced by ID, as well as products that belong directly to the category. Prob- ably all categories should be cached. They are often used and often traversed. The memory consumption of each cache entry should be small, but can increase if custom attributes are used.
product	Products and variants/SKUs altogether. Please note, there is no distinction between base products and variants/SKUs. Keep this in mind when choosing a capacity value! The memory consumption of each cache entry should be small, but can increase if custom attributes are used.
segments	The list of all customer segments referenced by ID.
segment	A customer segment with its properties. The memory consumption of each cache entry is very small.
marketingspots	The list of all marketing spots referenced by ID.
marketingspot	A marketing spot with its properties. The memory consumption of each cache entry is very small.

Vendor specific config keys:

previewtoken	Preview tokens to support the Studio preview of commerce pages. A new token is requested for each new combination of preview parameters (e.g. customer segments, preview date). The cache time should be less than the default expiration time in the commerce system.
storeinfo	The global store info with all available catalogs referenced by name and ID.
categoryid	Used to map tech IDs to external IDs of categories. The memory consumption of each cache entry is very small.
categorydata	Used to build storefront URLs and in services that are not already cached in the base adapter (e.g. PriceService, LinkSer vice, CartService). Each entry consumes ~10kB heap memory.
productid	Used to map tech IDs to external IDs of products and variants/SKUs. The memory consumption of each cache entry is very small.
productdata	Used to build storefront URLs and in services that are not already cached in the base adapter [e.g. PriceService, LinkSer vice, CartService]. Please note, there is no distinction between base products and variants/SKUs. Keep this in mind when choosing a capacity value! Each entry consumes ~100kB heap memory.
dynamicprice	To retrieve personalized prices for products and SKUs. Please note, there is no distinction between base products and variants/SKUs. Keep this in mind when choosing a capacity value! The memory consumption of each cache entry is small.
staticprice	To retrieve static list prices for products and SKUs. Please note, there is no distinction between base products and variants/SKUs. Keep this in mind when choosing a capacity value! The memory consumption of each cache entry is small.

The default values for the capacity and cache time of each cache key can be found in the in the application.properties file in the adapter or consult the Spring Boot environment actuator of the app.

Commerce Cache Configuration of Commerce Adapter Clients

NOTE

This chapter applies to Commerce Adapter clients like Studio, Content Application Engine, *Headless Server* and Content Feeder. Every commerce cache class has a default capacity and default cache time configured in the application. Each of the default values can be adapted to the needs of your system environment by overwriting the corresponding properties.

Refer to the Chapter 12, *Commerce Adapter Properties* [133] if you want to adjust the cache configuration for your Commerce Adapter

In order to adjust the cache configuration you can use the following properties [see Section 3.7, "Commerce Hub Properties" in *Deployment Manual* for details] for cache capacities and cache timeouts respectively:

- cache.capacities.ecommerce.*
- cache.timeout-seconds.ecommerce.*

ACTUATOR URLS		
Service	Actuator Shortcuts	Status
Content Management Server	Info · Logfile · Environment · Config · Health	HEALTHY
Master Live Server	Info · Logfile · Environment · Config · Health	HEALTHY
Workflow Server	Info · Logfile · Environment · Config · Health	HEALTHY
Content Feeder	$Info \cdot Logfile \cdot Environment \cdot Config \cdot Health$	HEALTHY
User Changes	$Info \cdot Logfile \cdot Environment \cdot Config \cdot Health$	HEALTHY
Elastic Worker	$Info \cdot Logfile \cdot Environment \cdot Config \cdot Health$	HEALTHY
CAE Feeder Preview	$Info \cdot Logfile \cdot Environment \cdot Config \cdot Health$	HEALTHY
CAE Feeder Live	$Info \cdot Logfile \cdot Environment \cdot Config \cdot Health$	HEALTHY

Figure 9.3. Actuator URLs in overview page

You have to replace the trailing "*" with the configuration key of the concrete cache key. You can find the keys and the default values using the Actuator URLs from the default overview page [https://overview.docker.localhost] in the default Blueprint Docker deployment. Click the *Config* link and search for the cache.capacities.ecommerce or cache.timeout-seconds.ecommerce prefix.

Figure 9.4. Actuator results for cache.timeout-seconds.ecommerce properties

10. The eCommerce API

The *eCommerce API* is a Java API provided by *CoreMedia Content Cloud* that can be used to build shop applications.

The *eCommerce API* is used internally to render catalog-specific information into standard templates. Furthermore, the Studio Library integration makes use of the API to browse and work with catalog items. If you develop your own shop application you will use the API in your templates and/or business logic (handlers and beans).

Various services allow you to access the eCommerce system for different tasks:

CatalogService	This service can be used to access the product catalog in many ways: traverse the category tree, products by category, various product and category searches.
MarketingSpotService	This service gives you access to Commerce e- Marketing Spots, a common method to use market- ing content [product teasers, images, texts] depend- ing on the customer segments.
SegmentService	This service lets you access customer segments, for example, the customer segments the current user is a member of.
CartService	This service lets you manage orders.
AssetService	This service lets you retrieve catalog assets, for example, product pictures or downloads, that are managed by the CMS. Unlike other services, this service only accesses the CMS.

The Commerce API includes some additional methods that denotes the vendor [the name, the version]. In *CoreMedia Studio* there is an option to open a management application for a commerce item [product or category]. The required base URL is also set through on the vendor specific connection.

The following key points will give you a short overview of the components that are also involved. They build up an infrastructure to bootstrap a connection to a commerce system and/or perform other supportive tasks.

Commerce

This class is the essential part of the bootstrap mechanism to access a commerce system. You

The eCommerce API |

can use it to create a connection to your commerce system.

- CommerceConnectionIni This class is used to initialize a request specific commerce connection. The resolved connection is stored in a thread local variable. The Commer ceConnection class provides access to all vendor specific eCommerce service implementations.
- CommerceBeanFactory This class creates CommerceBeans whose implementation is defined via Spring. It is also used by the services to respond service calls, for example, instances of Product and/or Cat egory beans. You can integrate your own commerce bean implementations via Spring (inheriting from the original bean implementation and place your own code would be a typical pattern).
- StoreContextProvider This class retrieves an applicable StoreCon text (the shop configuration that contains information like the shop name, the shop ID, the locale and the currency].
- UserContextProvider This class is responsible to retrieve the current UserContext.Some operations, like requesting dynamic price information, demand a user login. These requests can be made on behalf of the requesting user.User name and user ID are then part of the user context.
- CommerceIdProvider The class CommerceIdProvider is used to create CommerceId instances. The class CommerceId is able to format and parse references to resources in the commerce items. References to commerce items will be possibly stored in content, like a product teaser stores a link to the commerce product.

Commerce beans are cached depending on time. Cache time and capacity can be configured via Spring.

Please refer to the Javadoc of the Commerce class as a good starting point on how to use the *eCommerce API*.

11. *HCL Commerce* REST Services used by CoreMedia

CoreMedia Content Cloud uses REST services of the HCL Commerce Server to access content. Here you find a list of URLs used by Studio and CAE.

REST Services used by CoreMedia Studio

- http://<search_server>/search/resources/store/<stor eId>/categoryview/@top
- http://<search_server>/search/resources/store/<stor eId>/categoryview/%20?categoryIdentifier=<categoryIden tifier>

This search-based REST call allows slash character in the category identifier.

- http://<search_server>/search/resources/store/<stor eId>/categoryview/byId/<uniqueId>
- http://<search_server>/search/resources/store/<stor eId>/categoryview/byParentCategory/<uniqueId>
- http://<search_server>/search/resources/store/<stor
 eId>/productview/byCategory/<categoryId>
- http://<search_server>/search/resources/store/<stor
 eId>/productview/bySearchTerm/<term>
- http://<wc_server>/wcs/resources/store/<stor eId>/spot?q=byTypeAndName&qType=MARKETING&qName=<term>
- http://<wc_server>/wcs/resources/store/<stor eId>/spot?q=byType&qType=MARKETING
- http://<wc_server>/wcs/resources/store/<storeId>/seg ment/<uniqueId>
- http://<wc_server>/wcs/resources/store/<storeId>/seg ment
- http://<wc_server>/wcs/resources/coremedia/languagemap

Used to map langld to numeric value

• http://<wc_server>/wcs/resources/coremedia/storeinfo

Used to get the storeld and the catalog information from all available stores in HCL Commerce

- http://<wc_server>/wcs/resources/store/<storeId>/cata log
- http://<wc_server>/wcs/resources/store/<storeId>
- http://<wc_server>/wcs/resources/rest/admin/v2/stores

REST Services used by the CAE

- http://<wc_server>/wcs/resources/store/<stor
 eId>/price?q=byPartNumbers&partNumber=<partNumber>
- http://<search_server>/search/resources/store/<stor eId>/categoryview/%20?categoryIdentifier=<categoryIden tifier>

This search-based REST call allows slash character in the category identifier.

- http://<search_server>/search/resources/store/<stor eId>/categoryview/<SeoSegment>
- http://<search_server>/search/resources/store/<stor eId>/categoryview/byId/<uniqueId>
- http://<search_server>/search/resources/store/<stor eId>/productview/%20?partNumber=<productIdentifier>

This search-based REST call allows slash character in the product identifier.

- http://<search_server>/search/resources/store/<stor
 eId>/productview/byId/<uniqueId>
- http://<search_server>/search/resources/store/<stor
 eId>/productview/bySearchTerm/<term>
- https://<wc_server>/wcs/resources/store/<storeId>/lo ginidentity
- https://<wc_server>/wcs/resources/store/<storeId>/previewToken
- http://<wc_server>:<searchport>/search/re sources/store/<storeId>/productview/%20?partNum ber=<productIdentifier>

This search-based REST call allows slash character in the product identifier.

 http://<wc_server>/wcs/resources/store/<storeId>/user context/@self/contextdata

Used by Elastic Social

 https://<wc_server>/wcs/resources/store/<storeId>/per son/@self Used by Elastic Social

 https://<wc_server>/wcs/resources/store/<storeId>/seg ment

Used by Adaptive Personalization

- http://<wc_server>/wcs/resources/store/<stor eId>/cart/@self
- http://<wc_server>/wcs/resources/coremedia/languagemap Used to map langld to numeric value
- http://<wc server>/wcs/resources/coremedia/storeinfo

Used to get the storeld and the catalog information from all available stores in *HCL Commerce*

 http://<wc_server>/wcs/resources/store/<storeId>/cata log

wcs.always-use-master-category		
Туре	java.lang.Boolean	
Default	false	
Description	Determines that the master category is set on a product. A "master" category must exist in the master catalog and the sales catalog as well. If it is combined with cat- egoryValidationEnabled = true and if the master category cannot be loaded then the next valid category is returned. If set to "true" the master category is set on products.	
wcs.auth-header-name		
Туре	java.lang.String	
Default		
Description	The name of an authentication header the REST connector uses the access the WCS REST services.	
	Default is empty, no Authentication header is used.	
wcs.auth-header-value		
Туре	java.lang.String	
Default		
Description	The value of an authentication header the REST connector uses the access the WCS REST services.	
wcs.category-validation-enabled		
Туре	java.lang.Boolean	

Default	false	
Description	Determines that only a loadable category is set on a product. All eligible categories are loaded one after the other. The first one that is successful is used.	
	If set to "true" only a loadable category is set on products.	
wcs.default-l	ocale	
Туре	java.util.Locale	
Default		
Description	The default locale the REST connector is using if no locale is given.	
wcs.dynamic-pricing-enabled		
Туре	java.lang.Boolean	
Default	false	
Description	Determines if dynamic pricing is enabled.	
	If set to "true" the PriceRepository tries to get personalized prices from the WCS, otherwise an empty price list is returned.	
wcs.password		
Туре	java.lang.String	
Default		
Description	The service user password the REST connector uses to log in into WCS.	
	This is mandatory and must be set.	
wcs.search-engine		
Туре	com.coremedia.commerce.adapter.wcs.client.common.SearchEngineType	
Default		
Description	Configures the search engine type of the HCL Commerce System.	
	It is only used since HCL Commerce 9.1 and the search engine ES is used as the default.	

wcs.search-profile-prefix		
Туре	java.lang.String	
Default	CoreMedia	
Description	Configures the prefix of the HCL Commerce Search profile. For HCL Commerce 9.0 and older the prefix CoreMedia is used as the default search profile prefix. With HCL Commerce 9.1 the prefix should be set to HCL.	
wcs.search-url		
Туре	java.lang.String	
Default		
Description	The general WCS URL to access the search-based WCS REST services via http. If a REST service does not need secure access this url prefix is used.	
wcs.secure-search-url		
Туре	java.lang.String	
Default		
Description	The secure WCS URL to access the search-based WCS REST services via https. If a REST service needs secure access this url prefix is used.	
wcs.secure-url		
Туре	java.lang.String	
Default		
Description	The secure WCS URL to access the WCS REST services via https. If a REST service needs secure access this url prefix is used.	
wcs.single-value-search-facets		
Туре	java.util.List <java.lang.string></java.lang.string>	

Default	
Description	Configures the keys of the facets that that can only be added with a single value to product search requests.
	Should e.g. be configured with parentCatgroup_id_search when connecting to WCS 8.0, because it doesn't allow searching with multiple category facets.
wcs.url	
Туре	java.lang.String
Default	
Description	The general WCS URL to access the WCS REST services via http.
	If a REST service does not need secure access this url prefix is used.
wcs.username	
Туре	java.lang.String
Default	
Description	The service user the REST connector uses to log in into WCS.
	This is mandatory and must be set.
wcs.version	
Туре	java.lang.String
Default	
Description	The WCS version. Some WCS REST services are version specific.
wcs.cookie.user.filter-pattern	
Туре	java.lang.String
Default	WCP?+
Description	The regular expression pattern for which the client should filter the relevant cookies. This should narrow down the cookies on the client side to a subset of cacheable cookies.

wcs.cookie.user.filter-pattern-for

Туре

java.util.Map<java.lang.String,java.lang.String>

Default

Description Cookie filter pattern for specific environment. The structure of the Map should be: key=environment, value=cookie pattern. The environment is the hardcoded name of the entity param which must be configured on the CM App client side e.g. `commerce.hub.data.customEntityParams.environment=PREVIEW|LIVE``

Examples:

wcs.link.filter-pattern-for.preview=WCP? .+

wcs.link.filter-pattern-for.live=WC? .+

wcs.cookie.user.user-session-pattern

Туре	java.lang.String
Default	WCP?_USERACTIVITY_(-1002 \d+)
Description	 The regular expression pattern for the WCS user session cookie. See description for WC_USERACTIVITY_ID in: HCL Commerce Version 9 User Guide - Session management - WebSphere Commerce session cookies WebSphere Commerce Version 8 User Guide - Session management - WebSphere Commerce Session cookies
wcs.link.asset	-url
Туре	java.lang.String
Default	
Description	Asset URL prefix that is used to build asset links to shop images in the live system. Typically, a proxy url is set including protocol and possibly a context path prefix. Should only be set if the adapter does not need to distinguish environments. In this case no environment metadata.custom-entity-param-names parameter is required.
Examles:

https://shop-hcl.coremedia.vm

integration scenarios.

https://shop-preview-hcl.coremedia.vm

This and the further wcs.link properties are not needed when only connecting to HCL Commerce 9.1+ React stores.

wcs.link.asset-url-for Type java.util.Map<java.lang.String,java.lang.String> Default Description Asset URL prefixes which are used to build asset links to shop images for different environments Typically, a proxy url is set including protocol and possibly a context path prefix. The structure of the Map should be: {key=environment, value=url}. The environment is the hardcoded name of the entity param which must be configured in the CMS app, e.g. commerce.hub.data.custom-entity-params.environment=preview|live. IMPORTANT: The keys used here must match those used in the CMS app via commerce.hub.data.custom-EntityParams.environment={environment}. Examples: wcs.link.asset-url-for.preview=https://shop-preview-hcl.coremedia.vm wcs.link.asset-url-for.live=https://shop-hcl.coremedia.vm For configuration options see also documentation of wcs.link.storefront-url-for. This and the further wcs.link properties are not needed when only connecting to HCL Commerce 9.1+ React stores. wcs.link.link-templates Type java.util.Map<java.lang.String,java.lang.String> Default Description Map of StorefrontRef. Used to build shop urls for the Studio Preview and Content-Led

Known default lookup keys are defined in StorefrontRefKeysCommerceLed and StorefrontRefKeysContentLed. Only lookup keys in lowercase and without "_" are valid.

These patterns can include tokens which will be replaced. These tokens must be well known. The following tokens are predefined:

- {storefrontUrl} ... the current store front URL
- {storeld} ... the current store id
- {locale} ... the current locale in java format, eg. en_US
- {language} ... the current language in java format, eg. en
- {langld} ... the current language as WCS specific id, e.g. "-1" as default language
- {catalogId} ... the current catalog id
- {categoryId} ... the current category id
- {productId} ... the current product id
- {seoSegment} ... the current seo segment path (can contain path delimiters)

This and the further wcs.link properties are not needed when only connecting to HCL Commerce 9.1+ React stores.

wcs.link.link-templates.categorylinkfragment

Туре	java.lang.String
Default	CM {"parentCategoryId":"{parentCategoryId}","topCategoryId":"{topCategory-<br Id}","level":{level},"renderType":"url","categoryId":"{categoryId}","objectType":"category"} CM>
Description	Used to generate category page links into CoreMedia fragments.
wcs.link.link-	-templates.categorynonseourl
Туре	java.lang.String
Default	{storefrontUrl}/CategoryDisplay?categoryId={categoryTechId}&storeId={stor- eId}&langId={langId}&catalogId={catalogId}
Description	Non-seo-friendly shop URLs to category pages.
wcs.link.link-	-templates.categorypreviewurl
Туре	java.lang.String
Default	{storefrontUrl}/CategoryDisplay?categoryId={categoryTechId}&storeId={stor- eId}&langId={langId}&catalogId={catalogId}&newPreviewSession=true&previewToken={pre- viewToken}
Description	Used to build the preview URL to a category page.

wcs.link.link-templates.categoryseourl

Туре	java.lang.String
Default	{storefrontUrl}/{language}/{storeName}/{pageld}
Description	Used to build seo-friendly URLs to category pages.
wcs.link.link	-templates.checkoutredirecturl
Туре	java.lang.String
Default	{storefrontUrl}/OrderCalculate?calculationUsageId=-1&storeId={storeId}&update- Prices=1&catalogId={catalogId}&orderId=.&langId={langId}&URL=AjaxOrderItemDis- playView
Description	Used to build the redirect URL to the checkout page.
wcs.link.link	-templates.cmajaxlinkfragment
Туре	java.lang.String
Default	CM {"url":"{url}","renderType":"url","objectType":"ajax"} CM
Description	Used to generate ajax urls to CoreMedia contents into CoreMedia fragments.
wcs.link.link	-templates.cmcontentlinkfragment
Туре	java.lang.String
Default	CM {"externalSeoSegment":"{externalSeoSegment}","renderType":"url","object-<br Type":"content"} CM>
Description	Used to build links to shop pages displaying CoreMedia Articles and Channels into CoreMedia fragments.
wcs.link.link	-templates.cmcontentpreviewurl
Туре	java.lang.String
Default	{storefrontUrl}/{language}/{storeName}/cm/{seoSegment}?newPreviewSession=true&pre- viewToken={previewToken}
Description	Used to build the preview URL to a shop page which displays a CoreMedia content.

wcs.link.link-templates.cmcontenturl

Туре	java.lang.String
Default	{storefrontUrl}/{language}/{storeName}/cm/{seoSegment}
Description	Used to build seo-friendly URLs to shop pages displaying CoreMedia Articles and Chan- nels.
wcs.link.link	-templates.contractpreviewurl
Туре	java.lang.String
Default	true
Description	Used to build a preview url with a contract parameter.
wcs.link.link	-templates.externalpagenonseopreviewurl
Туре	java.lang.String
Default	{storefrontUrl}/{externalUriPath}&newPreviewSession=true&previewToken={previewToken}
Description	Used to build the preview URL to a shop page which has no seo support.
wcs.link.link	-templates.externalpagenonseourl
Туре	java.lang.String
Type Default	java.lang.String {storefrontUrl}/{externalUriPath}
Type Default Description	java.lang.String {storefrontUrl}/{externalUriPath} Used to build non-seo-friendly URLs to shop pages.
Type Default Description wcs.link.link	java.lang.String {storefrontUrl}/{externalUriPath} Used to build non-seo-friendly URLs to shop pages. -templates.externalpagepreviewurl
Type Default Description wcs.link.link- Type	java.lang.String {storefrontUrl}/{externalUriPath} Used to build non-seo-friendly URLs to shop pages. -templates.externalpagepreviewurl java.lang.String
Type Default Description wcs.link.link Type Default	java.lang.String {storefrontUrl}/{externalUriPath} Used to build non-seo-friendly URLs to shop pages. -templates.externalpagepreviewurl java.lang.String {storefrontUrl}/{language}/{storeName}/{pageld}?newPreviewSession=true&preview- Token={previewToken}
Type Default Description wcs.link.link Type Default Description	java.lang.String {storefrontUrl}/{externalUriPath} Used to build non-seo-friendly URLs to shop pages. -templates.externalpagepreviewurl java.lang.String {storefrontUrl}/{language}/{storeName}/{pageld}?newPreviewSession=true&preview- Token={previewToken} Used to build the preview URL to a shop page.

Туре	java.lang.String	
Default	{storefrontUrl}/{language}/{storeName}/{pageld}	
Description	Used to build seo-friendly URLs to shop pages.	
wcs.link.link	-templates.homepagelinkfragment	
Туре	java.lang.String	
Default	CM {"externalSeoSegment":"","renderType":"url","objectType":"page"} CM	
Description	Used to the link to the home page.	
wcs.link.link	-templates.homepagepreviewurl	
Туре	java.lang.String	
Default	{storefrontUrl}/{language}/{storeName}/{pageld}?newPreviewSession=true&preview- Token={previewToken}	
Description	Used to build the preview URL to the shop home page.	
wcs.link.link	-templates.loginurl	
Туре	java.lang.String	
Default	$\label{eq:storefrontUrl} \label{eq:storefrontUrl} eq:storefron$	
Description	Used to build the URL to the Login page.	
wcs.link.link-templates.logouturl		
Туре	java.lang.String	
Default	{storefrontUrl}/Logoff?storeId={storeId}	
Description	Used to build the URL which logs off the current user.	
wcs.link.link	-templates.productlinkfragment	
Туре	java.lang.String	

Default	CM {"productld":"{productld}","renderType":"url","categoryld":"{categoryld}","object-<br Type":"product"} CM>	
Description	Used to build product detail page links into CoreMedia fragments.	
wcs.link.link	-templates.productnonseourl	
Туре	java.lang.String	
Default	{storefrontUrl}/ProductDisplay?productId={productTechId}&storeId={stor- eId}&langId={langId}&catalogId={catalogId}	
Description	Url pattern that is used to build non-seo-friendly shop URLs to product detail pages.	
wcs.link.link	-templates.productpreviewurl	
Туре	java.lang.String	
Default	{storefrontUrl}/ProductDisplay?productId={productTechId}&storeId={stor- eld}&langId={langId}&catalogId={catalogId}&newPreviewSession=true&previewToken={pre- viewToken}	
Description	Used to build the preview URL to a product detail page.	
wcs.link.link	-templates.productseourl	
Туре	java.lang.String	
Default	{storefrontUrl}/{language}/{storeName}/{pageId}	
Description	Url pattern that is used to build shop URLs for product detail pages.	
wcs.link.link-templates.searchredirecturl		
Туре	java.lang.String	
Default	{storefrontUrl}/SearchDisplay?storeId={storeId}&catalogId={cata- logId}&langId={langId}&pageSize=12&searchTerm={searchTerm}	
Description	Used to build the parameterized search url to be redirected to the shop search result page.	
wcs.link.link	-templates.shoppagelinkfragment	

Туре	java.lang.String
Default	CM {"externalSeoSegment":"{externalSeoSegment}","externalUriPath":"{externalUri-<br Path}","renderType":"url","objectType":"page"} CM>
Description	Used to build URLs to shop pages into CoreMedia fragments.
wcs.link.prod	uct-max-url-segments
Туре	java.lang.Integer
Default	3
Description	Max url segments of an seo url for products
	This and the further wcs.link properties are not needed when only connecting to HCL Commerce 9.1+ React stores.
wcs.link.stor	efront-url
Туре	java.lang.String
Default	
Default Description	Storefront URL prefix that is used to build storefront links to shop pages and resources in the live system.
Default Description	Storefront URL prefix that is used to build storefront links to shop pages and resources in the live system. Typically, a proxy url is set, including protocol and possibly a context path prefix.
Default Description	Storefront URL prefix that is used to build storefront links to shop pages and resources in the live system. Typically, a proxy url is set, including protocol and possibly a context path prefix. Should only be set if the adapter does not need to distinguish environments In this case no environment metadata.custom-entity-param-names parameter is required.
Default Description	Storefront URL prefix that is used to build storefront links to shop pages and resources in the live system. Typically, a proxy url is set, including protocol and possibly a context path prefix. Should only be set if the adapter does not need to distinguish environments In this case no environment metadata.custom-entity-param-names parameter is required. Examples:
Default Description	Storefront URL prefix that is used to build storefront links to shop pages and resources in the live system. Typically, a proxy url is set, including protocol and possibly a context path prefix. Should only be set if the adapter does not need to distinguish environments In this case no environment metadata.custom-entity-param-names parameter is required. Examples: https://shop-hcl.coremedia.vm/webapp/wcs/shop
Default Description	Storefront URL prefix that is used to build storefront links to shop pages and resources in the live system. Typically, a proxy url is set, including protocol and possibly a context path prefix. Should only be set if the adapter does not need to distinguish environments In this case no environment metadata.custom-entity-param-names parameter is required. Examples: https://shop-hcl.coremedia.vm/webapp/wcs/shop
Default Description	Storefront URL prefix that is used to build storefront links to shop pages and resources in the live system. Typically, a proxy url is set, including protocol and possibly a context path prefix. Should only be set if the adapter does not need to distinguish environments In this case no environment metadata.custom-entity-param-names parameter is required. Examples: https://shop-hcl.coremedia.vm/webapp/wcs/shop https://shop-preview-hcl.coremedia.vm/webapp/remote/preview/servlet
Default Description	Storefront URL prefix that is used to build storefront links to shop pages and resources in the live system. Typically, a proxy url is set, including protocol and possibly a context path prefix. Should only be set if the adapter does not need to distinguish environments In this case no environment metadata.custom-entity-param-names parameter is required. Examples: https://shop-hcl.coremedia.vm/webapp/wcs/shop https://shop-preview-hcl.coremedia.vm/webapp/remote/preview/servlet This and the further wcs.link properties are not needed when only connecting to HCL Commerce 9.1+ React stores.

Type java.util.Map<java.lang.String,java.lang.String>

Default		
Description	Storefront URLs which are used to build storefront links to shop pages and resources for different environments. The structure of the Map should be: {key=environment, value=url}.	
	The multi-environment support needs to be activated via metadata.custom-entity- param-names=environment.	
	Examples:	
	wcs.link.storefront-url-for.preview=https://shop-preview-hcl.coremedia.vm/webapp/remote/preview/servlet	
	<pre>wcs.link.storefront-url-for.live=https://shop-hcl.coremedia.vm/webapp/wcs/shop</pre>	
	The environment name for the custom entity param must be configured on the client side [CAE, Studio, etc.]. Global configuration example: commerce.hub.data.customEnti-tyParams.environment=preview live	
	You may also configure multiple storefront URLs for different sites/environments via the commerce settings struct: commerce [Struct] customEntityParams [Struct] environ- ment=siteus [String] Keep the lookup keys simple. Use lowercase with no special char- acters.	
	Be aware that you need to configure the environment values on the client site first, otherwise lookups can't work and will fail. There is no default fallback as this could lead to even more confusion.	
	This and the further wcs.link properties are not needed when only connecting to HCL Commerce 9.1+ React stores.	
cache.capacities		
Туре	java.util.Map <java.lang.string,java.lang.long></java.lang.string,java.lang.long>	
Default		
Description	Number of cache entries per cache class until cache eviction takes place. The keys must match the cache classes as defined by the cache keys. Please refer to javadoc of com.coremedia.cache.CacheKey.	
cache.timeout	-seconds	
Туре	java.util.Map <java.lang.string,java.lang.long></java.lang.string,java.lang.long>	
Default		

Description	TTL in seconds until certain cache entries are invalidated.	
entities.circ	uit-breaker-names	
Туре	java.util.Map <java.lang.string,java.lang.string></java.lang.string,java.lang.string>	
Default		
Description	Mapping of data lookup keys (cache classes) to circuit breaker names. Mapping to 'none' disables circuit breakers for the mapped data lookup keys.	
	Example: Mapping 'product' to 'products' will use a separate circuit breaker named 'products' for product calls. The new circuit breaker can have its own configuration via 'resilience4j.circuitbreaker.configs.products'. Mapping 'product' to 'none' will disable the circuit breaker for product requests.	
entities.defa	ult-circuit-breaker-name	
Туре	java.lang.String	
Default	base	
Description	The default breaker name.	
entities.disal	ble-circuit-breakers	
Туре	java.lang.Boolean	
Default	false	
Description	Disable circuit breakers and cache failed calls in cache class failed.	
entities.exponential-backoff.factor		
Туре	java.lang.Double	
Default	1.5	
Description	The factor to be applied to the delay to compute the next delay.	
entities.expo	nential-backoff.initial-delay	
Туре	java.time.Duration	

Default	2s	
Description	The initial delay of the backoff.	
entities.mess	age-store.files	
Туре	java.util.Map <java.lang.string,java.lang.long></java.lang.string,java.lang.long>	
Default		
Description	The number of request/response pairs to cache persistently. The keys must be valid cache classes as configured for the data lookup service, e.g., catalog, catalogs, category, categories, etc.	
entities.mess	age-store.root	
Туре	org.springframework.core.io.Resource	
Default		
Description	Root resource to persistently store messages. If this property is not set, no messages will be persisted. Configure a value to enable persistent caching of messages.	
entities.prod	ucts.register-parent-dependency	
Туре	java.lang.Boolean	
Default	true	
Description	Controls if a parent dependency is registered for a non-base product so that it is inval- idated together with its base product.	
entities.recompute-on-invalidation		
Туре	java.lang.Boolean	
Default	false	
Description	Whether to recompute entities proactively on invalidation.	
entities.send	-invalidations	
Туре	java.lang.Boolean	

Default	true	
Description	Whether or not to propagate invalidations of entities to the clients.	
metadata.addi	tional-metadata	
Туре	java.util.Map <java.lang.string,java.lang.string></java.lang.string,java.lang.string>	
Default		
Description	Map of additional metadata.	
	Can be used as customization hook. All properties starting with "metadata.additional- metadata.*" are transmitted to the generic client on the CMS side.	
metadata.cust	om-attributes-format	
Туре	com.coremedia.commerce.adapter.base.entities.CustomAttributesFormat	
Default		
Description	Format of the custom attribute values.	
	The keys are always plain strings.	
	Used to identify the deserialization format on the CMS side.	
metadata.cust	om-entity-param-names	
Туре	java.util.Collection <java.lang.string></java.lang.string>	
Default		
Description	List of parameter names, which values need to be transmitted with every entity request from the CMS side.	
metadata.replacement-tokens		
Туре	java.util.Map <java.lang.string,java.lang.string></java.lang.string,java.lang.string>	
Default		
Description	Map of key value pairs.	
	Used as replacement map for example for link building in the generic client on the CMS side.	

metadata.vendo	or
Туре	java.lang.String
Default	
Description	Name of the vendor. Used to identify the connected vendor on the CMS side.

Table 12.1. HCL Commerce Adapter related Properties

Glossary

Approve	<i>CoreMedia CMS</i> contains a Content Management Environment for content creation and management and a Content Delivery Environment for content delivery. Content has to be published from the Management Environment to the Delivery Environment in order to become visible to customers. Before content can be published, it has to be approved. This way, <i>CoreMedia CMS</i> supports the dual control principle.
Blob	Binary Large Object or short blob, a property type for binary objects, such as graphics.
Content Delivery Environment	The <i>Content Delivery Environment</i> is the environment in which the content is de- livered to the end-user.
	It may contain any of the following modules:
	 CoreMedia Master Live Server CoreMedia Replication Live Server CoreMedia Content Application Engine CoreMedia Search Engine Elastic Social CoreMedia Adaptive Personalization
Content item	In <i>CoreMedia CMS</i> , content is stored as self-defined content items. Content items are specified by their properties or fields. Typical content properties are, for example, title, author, image and text content.
Content Management Environment	The <i>Content Management Environment</i> is the environment for editors. The content is not visible to the end user. It may consist of the following modules:
	 CoreMedia Content Management Server CoreMedia Workflow Server CoreMedia Importer CoreMedia Site Manager CoreMedia Studio CoreMedia Search Engine CoreMedia Adaptive Personalization CoreMedia Preview CAE
Content Management Server	Server on which the content is edited. Edited content is published to the Master Live Server.

Glossary |

Content Repository	<i>CoreMedia CMS</i> manages content in the Content Repository. Using the Content Server or the UAPI you can access this content. Physically, the content is stored in a relational database.
Content Server	<i>Content Server</i> is the umbrella term for all servers that directly access the Core- Media repository:
	Content Servers are web applications running in a servlet container.
	 Content Management Server Master Live Server Replication Live Server
Content type	A content type describes the properties of a certain type of content. Such properties are for example title, text content, author,
Control Room	<i>Control Room</i> is a <i>Studio</i> plugin, which enables users to manage projects, work with workflows, and collaborate by sharing content with other <i>Studio</i> users.
CoreMedia Studio	<i>CoreMedia Studio</i> is the working environment for business specialists. Its function- ality covers all the stages in a web-based editing process, from content creation and management to preview, test and publication.
	As a modern web application, <i>CoreMedia Studio</i> is based on the latest standards like Ajax and is therefore as easy to use as a normal desktop application.
Dead Link	A link, whose target does not exist.
Derived Site	A derived site is a site, which receives localizations from its master site. A derived site might itself take the role of a master site for other derived sites.
Elastic Social	<i>CoreMedia Elastic Social</i> is a component of <i>CoreMedia CMS</i> that lets users engage with your website. It supports features like comments, rating, likings on your website. <i>Elastic Social</i> is integrated into <i>CoreMedia Studio</i> so editors can moderate user generated content from their common workplace. <i>Elastic Social</i> bases on NoSQL technology and offers nearly unlimited scalability.
Folder	A folder is a resource in the CoreMedia system which can contain other resources. Conceptually, a folder corresponds to a directory in a file system.
Folder hierarchy	Tree-like connection of folders, where the root folder forms the origin of the tree.
Home Page	The main entry point for all visitors of a site. Technically it is often referred to as root document and also serves as provider of the default layout for all subpages.
IETF BCP 47	Document series of <i>Best current practice</i> (BCP) defined by the Internet Engineering Task Force (IETF). It includes the definition of IETF language tags, which are an abbreviated language code such as en for English, pt-BR for Brazilian Portuguese, or nan-Hant-TW for Min Nan Chinese as spoken in Taiwan using traditional Han characters.

Glossary |

Locale	Locale is a combination of country and language. Thus, it refers to translation as well as to localization. Locales used in translation processes are typically represented as IETF BCP 47 language tags.
Markup	Marking of parts of a document, structurally (section, paragraph, quote,) or with layout (bold, italic,).
Master Live Server	The Master Live Server is the heart of the Content Delivery Environment. It receives the published content from the Content Management Server and makes it available to the CAE. If you are using the CoreMedia Multi-Master Management Extension you may use multiple Master Live Server in a CoreMedia system.
Master Site	A master site is a site other localized sites are derived from. A localized site might itself take the role of a master site for other derived sites.
MIME	With Multipurpose Internet Mail Extensions (MIME), the format of multi-part, multi- media emails and of web documents is standardised.
Personalisation	On personalised websites, individual users have the possibility of making settings and adjustments which are saved for later visits.
Projects	With projects you can group content and manage and edit it collaboratively, setting due dates and defining to-dos. Projects are created in the Control Room and managed in project tabs.
Property	In relation to CoreMedia, properties have two different meanings:
	In CoreMedia, content items are described with properties (content fields). There are various types of properties, e.g. strings (such as for the author), Blobs (e.g. for images) and XML for the textual content. Which properties exist for a content item depends on the content type.
	In connection with the configuration of CoreMedia components, the system beha- vior of a component is determined by properties.
Publication	Creates or updates resources on the Live Server.
Resource	A folder or a content item in the CoreMedia system.
Responsive Design	Responsive design is an approach to design a website that provides an optimal viewing experience on different devices, such as PC, tablet, mobile phone.
Root folder	The uppermost folder in the CoreMedia folder hierarchy. Under this folder, CoreMedia users can add further folders and content items.
Site	A site is a cohesive collection of web pages in a single locale, sometimes referred to as localized site. In <i>CoreMedia CMS</i> a site especially consists of a site folder, a site indicator and a home page for a site.
	A typical site also has a master site it is derived from.

Glossary |

Site Folder	All contents of a site are bundled in one dedicated folder. The most prominent document in a site folder is the site indicator, which describes details of a site.
Site Indicator	A site indicator is the central configuration object for a site. It is an instance of a special content type, most likely CMSite.
Site Manager	Swing component of CoreMedia for editing content items, managing users and workflows.
	The Site Manager is deprecated for editorial use.
Site Manager Group	Members of a site manager group are typically responsible for one localized site. Responsible means that they take care of the contents of that site and that they accept translation tasks for that site.
Teaser	A short piece of text or graphics which contains a link to the actual editorial content.
Translation Manager Role	Editors in the translation manager role are in charge of triggering translation workflows for sites.
Variants	Most of the time used in context of content variants, variants refer to all localized versions within the complete hierarchy of master and their derived sites (including the root master itself).
Version history	A newly created content item receives the version number 1. New versions are created when the content item is checked in; these are numbered in chronological order.
Weak Links	In general <i>CoreMedia CMS</i> always guarantees link consistency. But links can be declared with the <i>weak</i> attribute, so that they are not checked during publication or withdrawal.
	Caution! Weak links may cause dead links in the live environment.
Workflow	A workflow is the defined series of tasks within an organization to produce a final outcome. Sophisticated applications allow you to define different workflows for different types of jobs. So, for example, in a publishing setting, a document might be automatically routed from writer to editor to proofreader to production. At each stage in the workflow, one individual or group is responsible for a specific task. Once the task is complete, the workflow software ensures that the individuals responsible for the next task are notified and receive the data they need to execute their stage of the process.
Workflow Server	The <i>CoreMedia Workflow Server</i> is part of the Content Management Environment. It comes with predefined workflows for publication and global-search-and-replace but also executes freely definable workflows.
XLIFF	XLIFF is an XML-based format, standardized by OASIS for the exchange of localiz- able data. An XLIFF file contains not only the text to be translated but also metadata about the text. For example, the source and target language. <i>CoreMedia Studio</i> allows you to export content items in the XLIFF format and to import the files again after translation.
